**FURFURYL-ETHYL-CARBINOL** *v.* **FURFURYL-PROPYL ALCOHOL**.

**FURFURYL-ETHYL-PYRIDINE**

*Hexahydrate*  $C_5H_6O \cdot CH_2 \cdot CH_2 \cdot C_5H_5N$ , (246°). From furfuryl-vinyl-pyridine and sodium in presence of alcohol (Merck, *B.* 21, 2709).—B'HCl: [145°–148°].—B'HBz. [c. 135°].—B'HI. [c. 121°].

**FURFURYLIDENE-ACETONE** *v.* **FURFURYL-VINYL METHYL KETONE**.

**FURFURYL-METHYLENE-DI-CARBAMIC ETHER**  $C_5H_6O \cdot CH(NH \cdot CO_2Et)_2$ . [169°]. Separates immediately on adding a drop of HClAq to a mixture of furfuraldehyde and carbamic ether (Bischoff, *B.* 7, 1081). Silky needles (from alcohol); insol. water, *v.* sol. alcohol and ether.

**FURFURYL-METHYLENE-MALONIC ACID**  $C_5H_6O \cdot CH:CH \cdot (CO_2H)_2$ . [187°]. From its ether. Prisms (from ether, alcohol, or HOAc); *v.* sol.

water, insol. benzene, light petroleum, and chloroform. Split up by heat into  $CO_2$  and furfuryl-acrylic acid. Reduced by sodium-amalgam to furfuryl-isosuccinic acid.

*Mono-ethyl ether EtHA'*. [103°]. Formed by gently heating the diethylether with potash. Trimetric prisms (from benzene). *V.* sl. sol. cold, *m.* sol. hot, water, *m.* sol. benzene and chloroform, insol. light petroleum. Split up by distillation into  $CO_2$  and furfuryl-acrylic acid.

*Di-ethyl ether Et $_2$ A'*. Formed by heating a mixture of furfuraldehyde and malonic ether with  $Ac_2O$  (Marckwald, *B.* 21, 1080). Oil; miscible with alcohol.

*Amide*  $C_5H_6O \cdot CH:CH \cdot C(ONH_2)_2$ . [180°]. Needles (from alcohol); *m.* sol. hot water, *v.* a. sol. HOAc, insol. ether.

**FURFURYL-DI-METHYL-PYRIDINE-DI-HYDRIDE DI-CARBOXYLIC ETHER**  $C_{11}H_{11}NO$ ,

by heating a mixture of furfuraldehyde and aceto-acetic ether with alcoholic  $NH_3$ . Colourless crystals. On oxidation it gives furfuryl-dimethyl-pyridine di-carboxylic acid (R. Schiff a. Puliti, *B.* 16, 1608).

**FURFURYL-NITRO-ETHYLENE**

$C_5H_6O \cdot CH:CH \cdot NO_2$ . [75°]. Formed by the action of furfuraldehyde upon an alkaline solution of nitromethane (Priebs, *B.* 18, 1862). Long yellow prisms. Easily volatile with steam. Gives on nitration  $C_5H_6(NO_2)_2O \cdot CH:CH \cdot NO_2$  [144°] which forms a crystalline dibromide [111°] and is oxidised by  $CrO_3$  to nitro-pyromucic acid.

**FURFURYL-PROPIONIC ACID**

$C_5H_6O \cdot CHMe \cdot CO_2H$ . [51°]. From furfuryl-acrylic acid by sodium amalgam (Baeyer, *B.* 10, 357). Sol. water and ether. Coloured yellow by HCl. Converted into furonic acid by successive treatment with Br and  $Ag_2O$ .

*Amide*  $C_5H_6O \cdot CHMe \cdot CONH_2$ . [98°]. (270°). Formed by heating the ammonium salt in a closed tube for some hours at 220° (Marckwald, *B.* 20, 2811). Needles, sol. water, alcohol, ether, and benzene, sl. sol. light petroleum.

**FURFURYL-PROPYL ALCOHOL**

$C_5H_6O \cdot CH(OH) \cdot C_2H_5$ . *Furfuryl-ethyl-carbinol*. (180° at 750 mm.). S.G.  $\frac{4}{4}$  1.066;  $\frac{15}{15}$  1.053. Formed by the action of zinc ethyl on furfuraldehyde and treatment of the product with water. Thick liquid (Pawlinoff a. Wagner, *B.* 17, 1968).

**(Py. 8.) FURFURYL-QUINOLINE**

$C_5H_5N \cdot C_5H_4O$ . [92°]. (above 300°). Formed by heating its carboxylic acid above its melting-point (Döbner, *A.* 242, 287). Long needles. Insol. cold, *v.* sl. sol. hot, water, *v.* a. sol. other ordinary solvents.

Salts.—(B'HCl) $_2$ PtCl $_4$  2aq: small yellow needles; sl. sol. cold, *v.* sol. hot, water.—B'HClAuCl $_4$ : lemon-yellow needles; sl. hot water.—B' $H_2Cr_2O_7$ : orange-red needles; sol. hot water.—Picrate: [186°]; large yellow plates.

(Py. 3). **FURFURYL-QUINOLINE** (Py. 1)-**CARBOXYLIC ACID**  $C_9H_7N(C_2H_5O)CO_2H$ . (Py. 3)-*Furfuryl-cinchonic acid*. [c. 215°]. Formed by heating together furfuraldehyde, pyruvic acid, and aniline in alcoholic solution (Döbner, A. 242, 285). Greenish-yellow needles. Sl. sol. cold, v. sol. hot water, v. s. sol. alcohol, ether, and benzene. Heated above its melting-point it yields (Py. 3)-furfuryl-quinoline.

**Salts**.—The Ag, Pb, and Cu salts are sl. sol. water. The chloride, nitrate, and sulphate, are v. sol. water.  $-(B'HCl)_2PtCl_6$ : orange-yellow needles; sl. sol. cold, v. sol. hot water.  $-(B'HCl)_3AuCl_3$ : lemon-yellow needles.

**FURFURYL-ISOSUCINIC ACID**  $C_9H_8O_4$ .  $CH_2(CO_2H)_2$ . [125°]. Formed by reducing furfuryl-methylene-malonie acid with sodium-amalgam (Marekwald, B. 21, 1080). Long slender needles, v. sol. water, ether, HOAc, and alcohol; almost insol. light petroleum. Split up by distillation into  $CO_2$  and furfuryl-propionic acid.

**FURFURYL-VALERIC ACID**  $C_9H_{12}O_4$ , i.e.  $C_9H_8O_4 \cdot CH_2 \cdot CH_2 \cdot CO_2H$ . Formed by reducing furfuryl-angelic acid by sodium-amalgam (Baeyer & Tönnies, B. 10, 1364; 12, 1200). Oil. By successive treatment with Br and  $Ag_2O$  it is converted into 'butyro-furonic acid'  $C_8H_8O_4$ .

**DI-FURFURYL-DI-VINYL KETONE**  $(C_6H_4O \cdot CH \cdot CH) \cdot CO$ . *Di-furfural-acetone*. [61°]. From furfuraldehyde (20 g.), acetone (6 g.), water (400 g.), alcohol (300 c.c.), and NaOH (3 g.) dissolved in water (27 g.). Flat lemon-yellow prisms, turning brown in air. V. sol. alcohol, ether, and chloroform, less sol. light petroleum. With conc.  $H_2SO_4$ , AcCl, or fuming HCl it gives dark-red solutions (Claisen & Ponder, A. 223, 146).

**FURFURYL-VINYL METHYL KETONE**  $C_9H_{10}O \cdot CH \cdot CH \cdot CO \cdot Me$ . *Furfural-acetone*. [40°]. (135°–137°) at 34 mm.; (229°) at 760 mm. From furfuraldehyde (20 g.), acetone (30 g.), water (1000 g.), and dilute (10 p.c.) NaOH (30 g.) left 24 hours in the cold, then extracted with ether and distilled. Yellow oil, smelling of cinnamon and of furfuraldehyde, but soon solidifies to thick prisms. V. sol. alcohol, ether, and chloroform, less sol. petroleum. In  $H_2SO_4$  it forms a brownish-yellow colour turning wine-red on heating. AcCl forms an orange liquid turning emerald-green (Claisen & Ponder, B. 14, 2468; A. 223, 145; J. G. Schmidt, B. 14, 1459).

**FURFURYL-(Py. 3)-VINYL-PYRIDINE**  $C_9H_8O \cdot CH \cdot CH \cdot C_4H_4N$ . [51°–53°]. From furfuraldehyde and (α)-methyl-pyridine at 165° in presence of a little ZnCl<sub>2</sub> (Merck, B. 21, 2709). Needles (from water); blackens in air; v. sol. alcohol and ether.  $-BHHgCl_2$  aq. [133°].  $-B'H_2PtCl_6$  2aq. [155°].  $-B'C_6H_5(NO_2)_2OH$ . [185°–190°]; yellow needles.

**FURFURYL-VINYL STYRYL KETONE**  $C_9H_8O \cdot CH \cdot CH \cdot CO \cdot CH \cdot CH \cdot Ph$ . *Furfural-benzylidene-acetone*. [56°]. From benzylidene-acetone (10 g.) and furfuraldehyde (7 g.), or from furfural-acetone (10 g.) and benzoic aldehyde (8 g.) in presence of water (200 g.), alcohol (130 g.), and dilute (10 p.c.) NaOH (10 g.).

**Properties**.—Straw-yellow plates (from boiling light petroleum). V. sol. alcohol, ether, benzene, and chloroform, less sol. petroleum. Conc.  $H_2SO_4$  forms a dark red, AcCl an orange solution (Claisen & Ponder, A. 223, 147).

**FURIL**  $C_{10}H_8O_4$ , i.e.  $C_6H_5O \cdot CO \cdot CO \cdot C_2H_5O$ . [162°]. Prepared by passing a stream of air through a solution of furin in alcoholic NaOH (E. Fischer, B. 13, 1337; A. 211, 221). Yellow needles. Insol. water, sl. sol. alcohol and ether, v. sol. chloroform. By sodium-amalgam it is reduced to furin. By aqueous KOH (1:2) it is converted into furilic acid. According to Jourdain (B. 16, 659) alcohol containing a little KCy gives furfuraldehyde and pyromucic ether.

**Furil-octo-bromide**  $C_{10}H_8O_4Br_8$ . [185°]. Crystalline. Sl. sol. alcohol, m. sol. chloroform. Prepared by the action of an excess of bromine on furil. On fusion it evolves Br and HBr, forming dibromo-furil and a small quantity of bromo-furil.

**Bromo-furil**  $C_{10}H_8BrO_4$ . [110°]? Yellow plates.

**Di-bromo-furil**  $C_{10}H_8Br_2O_4$ . [184°]. Sublimable. Golden yellow plates.

**Benz-furil** v. vol. i. p. 462.

**FURILIC ACID**  $(C_6H_5O)_2C(OH) \cdot CO_2H$ . Formed by rubbing furil with warm KOHq, adding dilute  $H_2SO_4$ , filtering from a separated resin, and extracting the filtrate with ether (E. Fischer, A. 211, 220). Unstable needles; decomposed at 100°; m. sol. cold water, v. sol. alcohol and ether. A resin slowly separates from the aqueous solution.

**Di-bromo-furilic acid**  $C_{10}H_8Br_2O_4$ . Formed by the action of baryta-water on di-bromo-furil. Its alcoholic solution is turned red by warming after addition of some dilute  $H_2SO_4$ .  $-BaA'$ : slender needles.

**FUROIN**  $C_8H_8O_4$ . [135°]. Prepared by boiling furfuraldehyde (40 g.), alcohol (30 g.), water (80 g.), and potassium cyanide (4 g.) for half an hour in a flask with inverted condenser. Crystallised from toluene or alcohol (E. Fischer, A. 211, 218; B. 13, 1334). Prisms. Distils unchanged. Sl. sol. hot water, alcohol, and ether. Conc.  $H_2SO_4$  forms a bluish-green colour. Weak acid. Gives an absorption spectrum. The solution in alcoholic NaOH is bluish-green, and is oxidised by the air to furil.

**Acetyl derivative**  $C_{10}H_8AcO_4$ . [76°]. Needles.

**FURONIC ACID**  $C_8H_8O_4$ . [180°]. Formed by adding bromine (1 mol.) to an aqueous solution of furfuryl-propionic acid (1 mol.), and treating the product with  $Ag_2O$  (6 mols.) (Baeyer, B. 10, 696, 1858). Colourless needles (from hot water). Sl. sol. cold water and ether. Conc.  $H_2SO_4$  forms a reddish-yellow solution. HClAq is not coloured by it. Hydriodic acid and red phosphorus at 200° reduce it to *n*-pimelic acid  $CO_2H \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CO_2H$ ? Sodium-amalgam gives hydrofuroic acid  $C_8H_8O_4$ .  $-Ag_2A'$ .

**Hydrofuroic acid**  $C_8H_8O_4$ . [112°]. Formed as above. Needles.  $-Ag_2A'$ : m. sol. hot water.

**FUSCO-SCLEROTIC ACID**  $C_8H_8O_4$ . An acid extracted by Dragendorff (C. C. 1878, 125, 141) from ergot by ether, the ergot having previously been treated with a solution of tartaric acid. It may be separated from 'picrosclerotic acid' by  $H_2SO_4$ , in which it is soluble (Blumberg, Ph. [8] 9, 28). Its alkaline salts are soluble.

**FUSSEL OIL**. A volatile liquid present in the product of the alcoholic fermentation of the saccharine liquids derived from potatoes, wheat,

&c., and of the juice of grapes, beet, &c. It passes over in the latter portion of the distillate when these liquids are rectified. Fusel oil always contains amyl and ethyl alcohols, usually isobutyl and *n*-propyl alcohols, some fatty acids, and some ethers.

Fusel oil from potatoes consists chiefly of isoamyl alcohol (*q. v.*); it often contains isobutyl alcohol and decolic acid (Dumas, *A.* 18, 80; Wurtz, *C. R.* 35, 310; *A.* 85, 197; Johnson, *J. pr.* 67, 262). Reibstein (*C. R.* 87, 501) found the following compounds in a litre of potato fusel oil: 275 c.c. isoamyl alcohol; 170 c.c. of products boiling above 132° and still containing amyl alcohol; 150 c.c. isopropyl alcohol; 125 c.c. water; 75 c.c. of a mixture of aldehyde, ethyl alcohol, and ethyl acetate; 66 c.c. *n*-butyl alcohol; 60 c.c. *sec*-amyl alcohol; 50 c.c. isobutyl alcohol; and 30 c.c. *n*-propyl alcohol.

Fusel oil from molasses contains isoamyl and isobutyl alcohols (Wurtz, *A.* 93, 107), together with palmitic (?) and heptioic acids and heptioic ether (Mulder, *J.* 1858, 302). Rowney (*C. J.* 4, 372) found isoamyl decolate as well as isoamyl alcohol, water, and EtOH in the fusel oil from the Scotch whisky distilleries.

In fusel oil obtained in preparing alcohol, partly from wheat, partly from maize, Wetherill (*Chem. Gaz.* 1853, 281) found acetic and octoic acids, isoamyl alcohol, but no butyl alcohol.

In the fusel oil from beet-root molasses Fehling (*J. Ph.* [3] 25, 74) found octoic and decolic acids and an ether of decolic acid. In a fusel oil from the same source Perrot (*C. R.* 45, 309; *A.* 105, 64) found ethyl, butyl, and isoamyl alcohols, compound ethers of the above alcohols with caproic, heptioic, octoic, and ennoic acids (*cf.* Müller, *J. pr.* 56, 103). Schrötter (*B.* 12, 1431) found in this fusel oil a liquid base  $C_8H_{17}O_2$ , (180°–230°) which forms a crystalline sulphate  $B'H_2SO_4$ . He also observed another base  $C_{11}H_{21}N_2$ .

**FUSIBLE METAL.** An alloy of Bi, Pb, and Sn, which melts at 93.7° (*v. vol.* i. p. 511).

**FUSTIC.** Two yellow dyes are known by this name, viz. *old fustic* obtained from *Morus tinctoria* and *young fustic* from *Rhus calamus*. The latter contains a glucoside 'fustin'  $C_{21}H_{32}O_{11}$ ? crystallising from water in needles [219°], and split up by dilute  $H_2SO_4$  into a sugar and Fisetin (*q. v.*) (Schmid, *B.* 19, 1735).

## G

**GALACTIN.** This name was given by Morin to a nitrogenous body resembling gelatin, said to occur in milk, blood, &c. (*J. Ph.* [3] 25, 423; [4] 14, 11). Wynter Blyth (*C. J.* 35, 531), after freeing milk from casein and albumen, and adding mercuric nitrate, obtained a pp. whence, after removal of mercury as sulphide, and ppg. a second time by lead acetate, a compound  $(PbO)_2C_6H_{12}N_2O_8$ ? was formed. After removing the lead an amorphous alkaloid was left, called by Blyth galactin. More recently the same name has been given by Muntz (*C. R.* 94, 453; *A. Ch.* [5] 26, 121; *Bl.* [2] 37, 409) to a non-nitrogenous carbohydrate  $C_6H_{10}O_5$  occurring in the seeds of leguminous plants. Muntz obtained it by exhausting powdered lucerneseeds, *Medicago sativa*, with water containing a little  $Pb(OAc)_2$ ; ppg. excess of lead by oxalic acid; diluting with alcohol (1½ vols.) and purifying the pp. by redissolving in water and reppg. with alcohol. When dried in the air it forms transparent nodules, which swell up in water and dissolve slowly like gum arabic, forming a sticky solution which is ppg. by basic, but not by normal, lead acetate, and behaves generally towards metallic salts like a solution of gum arabic. It is dextrorotatory,  $[\alpha]_D = 84.6^\circ$ .  $HNO_3$  oxidises it to mucic acid. Very dilute mineral acids at 100° give galactose and a non-crystalline sugar. Galactin is not inverted by saliva or pancreatic juice. A substance resembling this galactin occurs in agar-agar (Bauer, *J. pr.* [2] 30, 381).

**Paragalactin.** This name is given by Schulze a. Steiger (*B.* 20, 290) to the (impure) substance left after exhausting finely-powdered lupin seeds (*Lupinus luteus*) by ether, followed by very dilute cold potash. It constitutes 25 p.c. of the

Vol. II.

seed, is somewhat gelatinous, and is converted into galactose by boiling dilute acids. After treatment with hot 10 p.c. aqueous KOH alcohol gives a gelatinous pp. whence an acetyl derivative  $C_6H_8AcO_5$  can be obtained.

**GALACTONIC ACID**  $C_6H_8O_7$ . *Lactonic acid.* Small colourless deliquescent needles.

**Formation.**—By oxidation of milk-sugar (Barth a. Hlasiwetz, *A.* 122, 96; 158, 259), arabinose, or galactose (Kilian, *B.* 13, 2307; 14, 651, 2529; 18, 1552) with bromine.

**Preparation.**—A solution of 100 grms. of milk-sugar in 400 c.c. of 5 p.c. sulphuric acid is boiled for 4 hours and freed from  $H_2SO_4$  by  $Ba(OH)_2$ . The filtrate concentrated to 300 c.c. and cooled to about 35° is oxidised by treatment with 200 grms. of bromine; the yield is 70 p.c. of the theoretical.

**Reactions.**—By heating to 100° it is converted into its lactone  $C_6H_8O_6$ , by loss of  $H_2O$ . It is reduced by HI to the lactone of  $\gamma$ -oxy-*n*-hexoic acid.  $HNO_3$  oxidises it to mucic acid. Potash-fusion gives oxalic and acetic acid. Galactonic acid is slightly laevorotatory. It does not reduce Fehling's solution.

**Salts.**— $A'Na$  2aq.— $A'(NH_4)$ — $A'Ca$  5aq.— $A'Cd$  4aq. monoclinc needles (*B. a. H.*).— $A'Cd$  4aq.

**GALACTOSE v. SUGARS.**

**GALANGIN**  $C_{15}H_{16}O_5$ . [215°]. Occurs, together with camphoride and alpinin, in the galanga-root (Jahns, *B.* 14, 2807). Sublimes in part. Light-yellow tables or flat prisms (containing  $\frac{1}{2}C_2H_5OH$ ); needles (containing  $H_2O$ ). Sol. ether; S. (90 p.c. alcohol) 1.5; nearly insol. water. Dissolves in alkalis forming a yellow solution. Reduces alkaline silver and copper solu-  
Q Q

tions. On oxidation with  $\text{HNO}_3$  it gives benzoic and oxalic acids. —  $\text{C}_{15}\text{H}_{10}\text{O}_4\text{Pb}$ : amorphous orange pp.

**Tri-acetyl derivative**  $\text{C}_{15}\text{H}_5\text{O}_7(\text{OAc})_3$ : [142°]; colourless needles. Sol. alcohol, insol. water.

**Di-bromo-derivative**  $\text{C}_{15}\text{H}_2\text{Br}_2\text{O}_4$ . Yellow needles.

**GALBANUM**. A gum resin supposed to be the produce of *Babon Galbanum* or *Ferula erubescens*, and imported from Africa and Persia. Yellowish mass with bitter taste and strong smell. It gives a yellowish-red or violet colour with hydrochloric acid, and an orange colour with a solution of bleaching powder (Hirschsohn, *C. C.* 1877, 182). Yields on distillation with water a small quantity (7 p.c.) of terpene, S.G. 2.814, (160°),  $n_D^{20} = -18$  (Mössner, *A.* 119, 257). According to Wallach (A. 238, 81) oil of galbanum contains a sesquiterpene  $\text{C}_{15}\text{H}_{24}$ , whose hydrochloride  $\text{C}_{15}\text{H}_{24}\text{H}_2\text{Cl}$  melts at 118°. Potash-fusion forms resorcin. Contains about 66 p.c. resin, sol. alcohol, ether, and ligroin, and 25 p.c. gum, sol. water. The resin contains 72 to 74 p.c. carbon, and 8 to 8.5 p.c. hydrogen, and is sol. lime-water. Alcoholic HCl acting on the resin at 100° forms umbelliferon; this body is also formed by the dry distillation of galbanum and other resins formed by umbelliferous plants (Sommer, *Ar. Ph.* [2] 98, 1). The oily distillate from galbanum, when freed from umbelliferon by dilute KOH aq, has a splendid blue colour (289°); it is sol. alcohol, insol. aqueous alkalis, coloured green by alcoholic  $\text{FeCl}_3$ , resinsified by Br, and coloured yellowish-red by  $\text{HNO}_3$ . This blue oil appears to be identical with oil of chamomile (*q. v.*) (Kachler, *B.* 4, 36).

**GALPEINE**  $\text{C}_{15}\text{H}_{21}\text{NO}_3$ . [116°]. An alkaloid present in the *Angustura* bark. On evaporation of the mother liquor from the oxalate or sulphate of cusparine the salts of galpeine separate out. White prisms, soluble in petroleum, ether, and alcohol. Its salts are more soluble than those of cusparine; their solutions are of a greenish-yellow colour resembling uranium salts. —  $\text{B}'\text{H}_2\text{SO}_4$  7aq: [50°]; greenish-yellow prisms. — Hydrochloride: prisms with triangular base. —  $\text{B}'\text{H}_2\text{PtCl}_6$ : bright yellow pp. (Körner a. Böhringer, *G.* 18, 865).

**GALITANNIC ACID**  $\text{C}_{15}\text{H}_{10}\text{O}_5$  3aq. A variety of tannin said to occur in *Galium verum* and *G. Aparine* (Schwarz, *A.* 83, 57).

#### GALLACETONINE v. PYROGALLOL.

**GALLACETOPHENONE** v. **TRI-OXY-ACETOPHENONE**.

**GALLACTIC ACID**  $\text{C}_7\text{H}_8\text{O}_6$ ? Formed by boiling milk-sugar (200 g.) with cupric sulphate (1,200 g.) and  $\text{NaOHAq}$  (Bodeker a. Struckmann, *A.* 100, 267). Yellow syrup, miscible with water and alcohol, insol. ether. Ppd. by lime-water and by  $\text{Pb}(\text{OAc})_2$ . —  $\text{Ca}_2\text{A}^{10}$  8aq: flocculent pp. —  $\text{Hg}_2\text{A}^{10}$  8aq: amorphous pp. —  $\text{Pb}_2\text{A}^{10}$  6aq: powder.

**GALLEIN**  $\text{C}_{20}\text{H}_{12}\text{O}$ , i.e.  $\text{CO} \begin{smallmatrix} \text{C}_6\text{H}_4 \\ \diagup \quad \diagdown \\ \text{O} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{C}_6\text{H}_2(\text{OH})_2 \\ \diagup \quad \diagdown \\ \text{O} \end{smallmatrix} \text{O}_2$  (?). *Pyrogallol-phthalein*.

**Preparation**.—By heating phthalic anhydride (1 pt.) with pyrogallol (2 pts.) at 190°–200°; the fused mass is dissolved in alcohol, filtered, and water added to ppt. the gallein; it is best purified

by means of the acetyl-derivative (Baeyer, *B.* 4, 457, 555, 663; Buchka, *A.* 209, 249).

**Properties**.—Brownish-red powder or glistening, minute crystals with green reflex; sl. sol. hot, insol. cold, water, sol. alcohol, sl. sol. ether, insol. benzene. It dissolves in conc. sulphuric acid with dark-red colouration. Its solution in  $\text{NH}_4\text{Aq}$  and in lime- and baryta-water is violet. Dyes fabrics mordanted with iron or alumina a bluer shade than logwood.

**Reactions**.—1. With alkalis it forms salts, which separate in metallic glistening green crystals; with excess of alkali a blue or blue-violet colouration is produced; but acids reprecipitate unaltered gallein from this solution.—2. On reduction with potash and zinc-dust it yields at first hydrogallein, and then gallin.—3. On reduction in acid solution gallol  $\text{C}_{20}\text{H}_{12}\text{O}$  is formed.—4. Fused with potash anhydro-pyrogallolketone  $\text{CO} \begin{smallmatrix} \text{C}_6\text{H}_2(\text{OH})_2 \\ \diagup \quad \diagdown \\ \text{O} \end{smallmatrix} \text{O}$  is produced.—5. With concentrated sulphuric acid at 190° it yields oerulein (*q. v.*).—6.  $\text{HNO}_3$  oxidises it to phthalic acid.

**Tetra-chloro-gallein**  $\text{C}_{20}\text{H}_2\text{Cl}_4\text{O}$ , 2aq (at 100°). Formed by heating tetra-chloro-phthalic anhydride with pyrogallol at 195° (Graebe, *A.* 238, 337). Violet powder.

**Di-bromo-gallein**  $\text{C}_{20}\text{H}_2\text{Br}_2\text{O}$ . Formed by adding Br to a solution of gallein in HOAc. Golden crystals with metallic lustre, v. sol. alcohol, sl. sol. benzene. Its solution in  $\text{NaOHAq}$  is brilliant blue.

**Constitution of Gallein**. The formula

was at first assigned to gallein from its analogy in its method of preparation to phenol-phthalein, and the formation of a tetracetyl derivative. But its behaviour with reducing agents is not thus explained; in contact with potash and zinc-dust it takes up two atoms of hydrogen, and the product should, were the above formula correct, be analogous to phenol-phthalin and possess acid properties. But the hydrogallein shows no acid properties, though on further reduction it yields an acid substance, converted by sulphuric acid into oerulein, the analogue of phenol-phthalidin. Gallein is thus possibly a peroxide, a view confirmed by the fact that the tetracetyl derivatives of gallein and hydrogallein are identical (Buchka, *A.* 209, 249).

**Hydrogallein**  $\text{C}_{20}\text{H}_{14}\text{O}$ , i.e.

reduction of gallein (*v. supra*). Crystalline powder, sol. alcohol and HOAc, sl. sol. water, insol. benzene. It dissolves in alkalis with blue colouration; the solution becomes red through oxidation if boiled for a long time.

**Tetra-acetyl derivative**  $\text{C}_{20}\text{H}_2\text{Ac}_4\text{O}$ , [248°]. Formed by boiling hydrogallein with  $\text{Ac}_2\text{O}$ , or by heating gallein with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$ . Small rhombohedra (from benzene); sol. alcohol and HOAc, insol. ether. Gives with Br in HOAc a di-bromo-derivative  $\text{C}_{20}\text{H}_2\text{Br}_2\text{Ac}_2\text{O}$ , [234°].

**Tetra-benzoyl derivative**  $\text{C}_{20}\text{H}_2\text{Bz}_4\text{O}$ , [231°]. Formed by boiling gallein with  $\text{BzCl}$ . Slender needles (from acetone); sol. alcohol and benzene.

Gallin  $C_{10}H_8O_4$ , i.e.  
 $CO_2.H_2C.H_4.CH < \begin{smallmatrix} C_6H_4(OH) \\ C_6H_3(OH)_2 \end{smallmatrix} > O(?)$ . Formed by reduction of gallein (q.v.). Small colourless needles, turning red on exposure, sol. alcohol and acetone, sl. sol. water. Decomposes carbonates; converted by conc. sulphuric acid into cærulein.

*Tetra-acetyl derivative*  $C_{26}H_{16}Ac_4O_{10}$ : [220°]; colourless leaflets (Buchka, A. 209, 268).

Gallein and gallin dye mordanted fabrics like barwood and logwood.

**GALLIC ACID**  $C_6H_4(OH)_3(CO_2H)$  [5:4:3:1]. Mol. w. 170. [220°-240°]. S. 1 (in the cold); 33 at 100°; S. (ether) 2.5 at 15°; S. (alcohol) 28 at 15°. S.G. 1.4604 (Schröder).

*Occurrence*.—In gall-nuts, in sumach, in hellebore root, in dividivi, in the acorns of *Quercus Agilops*, in green and black tea, in leaves of *Arctostaphylos uva-ursi*, in sandalwood, in colchicum, in strychnos bark, walnuts, and in most astringent parts of plants (Scheele; Stenhouse, A. 45, 9; Kawalier, Sitz. W. 9, 290; Hlasiwetz a. Malin, Z. 1867, 271; Phipson, C. N. 20, 116; Bolley a. Bahr, Z. [2] 4, 501).

*Formation*.—1. By exposing powdered gall-nuts to the air for a month at 20° to 25°; the powder, which must be kept moist, becomes covered with mould, which must be constantly removed, and the product, as soon as the aqueous extract ceases to ppt. a solution of gelatin, is exhausted with water (Scheele; Steer, Sitz. W. 22, 249; Wittstein, Ph. 12, 444; cf. Tieghem, C. R. 65, 1091; Weber, Ph. [3] 10, 754).—2. A solution of tannin is pptd. by conc.  $H_2SO_4$  and the pp. added to boiling dilute  $H_2SO_4$ ; after a few minutes gallic acid is deposited in crystals (Liebig).—3. By the action of hot conc.  $KOH$  on di-iodo-salicylic acid; a considerable portion of the gallic acid being, however, converted into pyrogallol (Lautemann, A. 120, 317). Demole (B. 7, 1441) could not obtain gallic acid in this way.—4. By the action of aqueous  $KOH$  on bromo-veratric acid (Matsumoto, B. 11, 139). The acid so prepared melted at 197°-200°.—5. By *potash-fusion* from di-iodo-*p*-oxy-benzoic, bromo-protocatechuic, and bromo-*s*-di-oxy-benzoic acids (Barth a. Senhofer, B. 8, 754, 1477; A. 142, 247; 164, 118).—6. By heating gum kino with conc.  $HCl$  at 120° (Etti, B. 11, 1882).

*Separation from tannin*.—An infusion of a plant which contains tannin and gallic acid is pptd. by gelatin; the filtrate is evaporated to dryness and exhausted with alcohol; the alcoholic extract is evaporated and the residue crystallised from water, being, if necessary, treated with animal charcoal.

*Properties*.—Long silky needles or triclinic prisms (containing aq.). Astringent taste but no smell. Its solution is strongly acid. At 100°-120° it gives off its water of crystallisation; at 215° it begins to decompose into  $CO_2$  and pyrogallol; but if rapidly heated to 250° there is formed, instead of pyrogallol, a black lustrous insoluble mass, soluble in alkalis (so-called 'Metagalloic acid'). An aqueous solution of gallic acid does not change if excluded from the air, but in the presence of oxygen  $CO_2$  is evolved and a black substance is deposited. This decomposition is hastened by the presence of alkalis. Boiling with excess of  $KOH$  gives a black sub-

stance, the so-called 'taurumelanolic acid.' Dilute alcoholic  $KOH$  gives 'galloflavin.' A solution of ammonium picrate gives a red colour changing to a beautiful green (Dudley, Am. 2, 48). Gallic acid reduces Fehling's solution and ammoniacal  $AgNO_3$ . Ferric chloride gives a bluish-black pp. (Chavreul, P. 17, 176); the pp. dissolves in excess of  $FeCl_3$  giving a green solution (Wackenroder, A. 31, 78; Etti, B. 11, 1882); on heating  $CO_2$  is evolved, the liquid becomes colourless and contains ferrous salt. Pure ferrous sulphate gives no colour at first, but the liquid presently becomes blue. With a mixture of  $FeCl_3$  and  $K_2FeC_4$ , gallic acid, like other reducing agents, ppts. Prussian blue. Pure gallic acid does not ppt. gelatin nor alkalis; but when mixed with gum it gives a pp. with gelatin. It gives no pps. with albumen, gelatinised starch or alkaloids, but tartar emetic and  $NH_4Cl$  give a heavy white pp. (Meissner, Ph. 1889, 626). A solution of gallic acid containing  $CaCO_3$  dissolved in  $CO_2$  becomes blue when exposed to the air. A solution of barium gallate gives with excess of  $AgNO_3$  a black pp. of silver, and the filtrate contains an acid resembling quercitanic acid (Löwe, J. pr. 102, 111; Barford, J. pr. 102, 314). If a solution of barium gallate  $BaA_2$  be treated with excess of baryta-water a white pp. is formed which quickly turns blue in contact with the air; but if the ppn. and washing be done with de-aerated water in an atmosphere of hydrogen, the pp. quickly dried *in vacuo* exhibits the composition  $BaC_6H_3O_5$  (Hlasiwetz, J. pr. 101, 113). An aqueous or alcoholic solution of gallic acid, containing  $Na_2SO_4$ , is coloured by iodine a transient purple-red (Nasse, B. 17, 1166).  $KCy$  colours an aqueous solution of gallic acid red (difference from tannin); the colour disappears on standing but reappears again on shaking with air (Young, Fr. 23, 227).

*Reactions*.—1. The crystallised acid is unacted on by cold acetic anhydride and even at 100° 2 g. require 2 hours for complete solution. The anhydrous acid behaves similarly towards cold anhydride, but the same quantity only requires  $\frac{1}{2}$ -hour for solution at 100°. The products are in the first case almost entirely the triacetyl derivative of gallic acid, whereas in the second case there is formed in addition to this a body [151°] having the properties of the pentacetyl derivative of tannin (Böttiger, A. 246, 125).—2. Aqueous  $KMnO_4$  is quickly decolourised by gallic acid, so that it may be estimated volumetrically in the same way as oxalic acid (Morin, C. R. 45, 677). When rubbed with dry  $KMnO_4$  it even takes fire (Böttiger, P. Jubelband, 166). Dilute  $H_2SO_4$  and  $KMnO_4$  in the cold give  $C_6H_4O_6$ , 'hydrorufgallic acid' a golden crystalline compound which gives a crimson colour with the alkalis and their carbonates (Oser a. Kalmann, M. 2, 50).—3. Completely oxidised to  $CO$  and  $CO_2$  by electrolytic oxygen (Bourgoin, J. Ph. [4] 13, 376). *Chromic acid mixture* acts in like manner (Remsen, Am. S. [3] 5, 354).—4. An aqueous solution of  $KClO_4$  and  $HCl$  gives iso-trichloro-glyceric acid  $C_3H_2Cl_3O_4$  (Schreder, A. 177, 282). If the mother-liquor from which the iso-trichloro-glyceric acid has crystallised be boiled with tin and  $HCl$ , the tin pptd. by  $H_2S$ , and the liquid extracted by ether, prisms of  $C_3H_2Cl_3O_4$  are got.

It forms the salts:  $\text{CaH}_2\text{A}''$ : minute needles;  $\text{BaA}'\text{aq}$ ; and  $\text{BaH}_2\text{A}'$ , 13aq.—6. By heating with bromine at  $100^\circ$  it is converted into tri-bromo-pyrogallol (Stenhouse, *A.* 177, 189).—6. Soda-fusion gives pyrogallol, hexa-oxy-diphenyl, and some phloroglucin (Barth a. Schreder, *B.* 12, 1259; *M.* 3, 649).—7. Hot  $\text{H}_2\text{SO}_4$  converts it into rufigallio acid  $\text{C}_6\text{H}_2\text{O}_7$  (v. Hexa-oxy-ANTHRAQUINONE).—8.  $\text{K}_2\text{S}_2\text{O}_8$  acting upon a solution of gallic acid in concentrated aqueous KOH forms  $\text{C}_6\text{H}_2(\text{OH})_2(\text{O}.\text{SO}_3.\text{OK})(\text{CO}.\text{K})$  which crystallises in slender needles (Baumann, *B.* 11, 1916). A mixture of gallic and benzoic acids is converted by  $\text{H}_2\text{SO}_4$  into anthragallol  $\text{C}_{12}\text{H}_6\text{O}_8$  (Seuberlich, *B.* 10, 38), v. TRI-OXY-ANTHRAQUINONE.—9. Gallic acid is converted by warming with phosphorus oxychloride for some hours into digallic acid  $\text{C}_6\text{H}_2(\text{OH})_2.\text{CO}.\text{O}.\text{C}_6\text{H}_2(\text{OH})_2.\text{CO}.\text{H}$  which is probably identical with tannin (Schiff, *A.* 170, 49).—10. Gallic acid (12 pts.) is converted by heating with cinnamic acid (10 pts.) and  $\text{H}_2\text{SO}_4$  (150 pts.) at  $50^\circ$  into styrogallol  $\text{C}_{12}\text{H}_6\text{O}_8$  (E. Jacobsen a. Julius, *B.* 20, 2538).—11. By heating with ammonium carbonate in a sealed tube an acid  $\text{C}_6\text{H}_2\text{O}_8$  is formed.—12. Formic aldehyde forms  $\text{C}_{12}\text{H}_{12}\text{O}_{10}$  and  $\text{C}_{12}\text{H}_{10}\text{O}_{11}$  (Bayer, *B.* 5, 1096).—13. By heating with arsenic acid to  $120^\circ$  ellagic acid  $\text{C}_{12}\text{H}_6\text{O}_8$  is formed (Löwe, *Z.* [2] 4, 603). If the product insoluble in water and consisting chiefly of ellagic acid be treated with sodium-amalgam, acidified, and shaken with ether, several substances are extracted, viz.: two crystalline substances  $\text{C}_{12}\text{H}_6\text{O}_8$  and  $\text{C}_{12}\text{H}_6\text{O}_{10}$ , both sl. sol. water, and a more soluble crystalline body (Rembold, *A.* 156, 116).

**Salts.**— $\text{NH}_4\text{A}'\text{aq}$ : slender needles (from water). Obtained by passing  $\text{NH}_3$  into an alcoholic solution of gallic acid.— $\text{KHA}'\text{aq}$ : prepared by adding an alcoholic solution of KOH gradually to an alcoholic solution of gallic acid until the pp. begins to be permanent; the liquid is then shaken, when a flaky pp. separates. The pp. is washed with alcohol, dissolved in water, concentrated, and ypd. by alcohol in colourless needles (Büchner, *A.* 53, 187).— $\text{NaA}'\text{3aq}$ : slender needles; prepared as the K salt.— $\text{BaA}'\text{3aq}$ : prepared by neutralising a boiling solution of gallic acid with  $\text{BaCO}_3$ , filtering, and rapidly concentrating. Small plates; sl. sol. water, insol. alcohol.— $\text{Ba}_2\text{C}_6\text{H}_2\text{O}_8\text{5aq}$ : v. *supra*.— $\text{SrA}'\text{4aq}$ : small needles; prepared like the Ba salts; sl. sol. water, insol. alcohol.— $\text{CaA}'\text{2aq}$ : crusts of adherent needles; prepared like the Ba salt.— $\text{MgC}_6\text{H}_2\text{O}_8\text{2aq}$ : obtained by boiling magnesium acetate with excess of gallic acid, evaporating to dryness, and treating with alcohol to remove free gallic acid. Light white powder; sl. sol. water.— $\text{Mg}_2(\text{C}_6\text{H}_2\text{O}_8)_2\text{6aq}$ .— $\text{Al}(\text{C}_6\text{H}_2\text{O}_8)_3\text{4aq}$ ? Flocculent pp. S. 202 qt  $20^\circ$ ; 84 at  $100^\circ$  (Lidoff, *J. R.* 1882, 195; *C. J.* 42, 849).— $\text{ZnC}_6\text{H}_2\text{O}_8\text{ZnO}$ : deposited as a bulky white pp. when gallic acid is added to a solution of zinc acetate.— $\text{CoC}_6\text{H}_2\text{O}_8\text{3aq}$ : crimson powder.— $\text{MnC}_6\text{H}_2\text{O}_8\text{aq}$ : crystalline powder, turns brown in air.— $\text{PbC}_6\text{H}_2\text{O}_8\text{4aq}$ : obtained as a white pp. which becomes crystalline by adding lead acetate to an excess of a boiling solution of gallic acid (Liebig, *A.* 26, 128).— $\text{Pb}_2(\text{C}_6\text{H}_2\text{O}_8)_2\text{PbO}$ : yellow crystalline salt; formed by boiling the preceding pp. in its mother liquor.— $\text{SnC}_6\text{H}_2\text{O}_8\text{SnO}$ : white crystalline powder, obtained by adding

gallic acid to a solution of  $\text{SnCl}_4$ , previously neutralised by  $\text{NH}_3$ .

**Acetyl derivative**  $\text{C}_6\text{H}_2(\text{OAc})_3.\text{CO}.\text{H}$  [166°]. Formed by boiling gallic acid with  $\text{AcCl}$  or  $\text{Ac}_2\text{O}$  (Nachbaur, *J. pr.* 72, 431; Schiff, *A.* 163, 209; Böttiger, *A.* 246, 125). Prisms (from water); sl. sol. hot water, v. sol. alcohol and ether. Gives no colour with  $\text{FeCl}_3$ .

**Bromo-acetyl derivative**  $\text{C}_6\text{H}_2(\text{OH})_2(\text{O}.\text{C}_6\text{H}_4.\text{BrO}).\text{CO}.\text{H}$ . From gallic acid and bromo-acetyl bromide (Priwoznik, *B.* 3, 644). Amorphous.

**Benzoyl derivative**  $\text{C}_6\text{H}_2(\text{OBz})_3.\text{CO}.\text{H}$ . Amorphous; softens at  $85^\circ$  (Schiff).

**Methyl ether**  $\text{C}_6\text{H}_2(\text{OH})_2.\text{CO}.\text{Me}$ . [192°]. V. sol. water and alcohol (Will, *B.* 21, 2020).

**Tri-methyl derivative**  $\text{C}_6\text{H}_2(\text{OMe})_3.\text{CO}.\text{H}$  [167°]. Needles (from ether or water) (W.).

**Methyl ether of the trimethyl derivative**  $\text{C}_6\text{H}_2(\text{OMe})_3.\text{CO}.\text{Me}$  [81°]. [275°]. (W.).

**Ethyl ether**  $\text{C}_6\text{H}_2(\text{OH})_2.\text{CO}.\text{Et}$ . [141°] (Etti, *B.* 11, 1882); [150°] (E. a. Z.); [158°] (G.). Formed by passing HCl into a solution of gallic acid (1 pt.) in alcohol (4 pts. of 80 p.c.), evaporating at  $70^\circ$  until the liquid gets thick, adding  $\text{BaCO}_3$ , and extracting the solid mass with ether (Grimaux, *Bl.* [2] 2, 94; Schiff, *A.* 163, 217). Prisms (containing 2½ aq) or anhydrous crystals (from chloroform) (Ernst a. Zwenger, *A.* 159, 28). [90°] when hydrated; [140°–158°] when anhydrous. Sl. sol. cold, v. sol. hot water; v. sol. alcohol and ether; v. sl. sol.  $\text{CHCl}_3$ . Gives a blue pp. with  $\text{FeCl}_3$ . Reduces ammoniacal  $\text{AgNO}_3$  and  $\text{AuCl}_3$ . Split up by dry distillation into alcohol,  $\text{CO}_2$ , and pyrogallol. An aqueous solution saturated by  $\text{NaHCO}_3$  gives small crystals of  $\text{C}_6\text{H}_2\text{NaEtO}_3.\text{C}_6\text{H}_4\text{P}4\text{O}$ . Sl. sol. cold water; on heating with water sodium ellagate  $\text{C}_6\text{H}_2\text{NaO}_3$  separates. Gallic ether gives a pp. with aqueous  $\text{Pb}(\text{OAc})_2$ , which when dried at  $100^\circ$  has the composition  $\text{Pb}_2(\text{C}_6\text{H}_2\text{EtO}_3)_2$ .

**Tri-acetyl derivative of the ethyl ether**  $\text{C}_6\text{H}_2(\text{OAc})_3.\text{CO}.\text{Et}$ . Oil, slowly becoming crystalline. Forms no pp. with lead salts.

**Isoamyl ether**  $\text{C}_6\text{H}_2(\text{OH})_2.\text{CO}.\text{C}_4\text{H}_9$ . [139°]. Slender glittering needles; sl. sol. cold water, v. sol. alcohol and ether.

**Tri-ethyl-gallic acid**  $\text{C}_6\text{H}_2(\text{OEt})_3.\text{CO}.\text{H}$ . [112°]. Colourless crystals. Sol. hot, sl. sol. cold, alcohol. Formed by boiling its ethyl-ether with alcoholic KOH. Salts.— $\text{A}'\text{Ag}$ : [c.  $200^\circ$ ]; crystalline solid; sl. sol. cold water.— $\text{A}'_2\text{Ba}$ : very soluble crystals. **Ethyl ether**  $\text{C}_6\text{H}_2(\text{OEt})_3.\text{CO}.\text{Et}$ : [51°]; glistening needles; v. sol. alcohol, ether, and benzene. Formed by heating the ethyl-ether of gallic acid with ethyl iodide and alcoholic KOH (Will a. Albrecht, *B.* 17, 2099).

**Amide**  $\text{C}_6\text{H}_2(\text{OH})_2.\text{CONH}_2$ . [248°]. Formed by the action of ammonia and ammonium sulphite on a moderately concentrated alcoholic solution of tannin, the crude product being fractionally crystallised from hydrochloric acid (A. a. W. Knop, *J. pr.* 56, 329; H. Schiff a. Pons, *G.* 15, 177; *B.* 18, 487). Large plates (containing 1½ aq); sl. sol. cold water. Completely decomposed at  $245^\circ$ . Does not combine with HCl. Decomposed by boiling with acids or alkalis into gallic acid

and  $\text{NH}_3$ . The lead compound is a heavy white powder, the copper compound

$\text{C}_6\text{H}_3(\text{OH})(\text{O.Cu})\text{CONH}_2$  is an azure-blue powder. The acetyl derivative  $\text{C}_6\text{H}_3(\text{OAc})_2\text{CONH}_2$  forms aggregates of colourless crystals,  $[\alpha]_{\text{D}}^{20}$  sol. water, alcohol, HOAc, and benzene.

**Bromo-gallic acid**  $\text{C}_6\text{HBr}(\text{OH})\text{CO}_2\text{H}$ . [above 200°]. Formed, together with the di-bromo-acid, by rubbing gallic acid with bromine (Grimaux, *Bl.* [2] 7, 479; Hlasiwetz, *A.* 142, 250). Monoclinic plates or needles (from water); sl. sol. cold water. Coloured by lime or baryta-water successively red, greenish, and orange.  $\text{FeCl}_3$  colours it blue-black; alkalis give an orange-yellow colour.

**Di-bromo-gallic acid**  $\text{C}_6\text{Br}_2(\text{OH})\text{CO}_2\text{H}$ . [140°] (G.); [150°] (Eti). Formed as above, using excess of Br. Long brittle needles or plates (containing aq at 100°). Sl. sol. cold water; coloured successively rose, light green, and dark red by lime or baryta-water. Its ethereal solution is turned indigo-blue by baryta-water. Alkalis form an orange solution, turned rose-red on dilution.  $\text{FeCl}_3$  gives a blue-black solution. With  $\text{Ag}_2\text{O}$  it gives  $\text{CO}_2$  and pyrogallol (Priwoznik, *B.* 3, 644).  $\text{AcCl}$  gives a tetra (?) acetyl derivative crystallising in needles [91°] (P.).

#### GALLIN v. GALLEIN.

**GALLISIN**  $\text{C}_{12}\text{H}_{22}\text{O}_{10}$ .  $[\alpha]_{\text{D}}^{20} = 77.3-82.7$ . The cupric reducing power of 10.98 grams = that of 5 grams of glucose. Occurs in commercial glucose (starch sugar), from the unferrmentable residue of which it is obtained by evaporating to a syrup and repeatedly treating with absolute alcohol, and finally with a mixture of alcohol and ether, till all the water has been removed, leaving the substance as a fine powder. White amorphous powder. Very deliquescent. Not fermentable by yeast. Slightly sweet insipid taste. It is insoluble in ether, very slightly in absolute alcohol, more easily in methyl alcohol and acetic acid. It gives no pps. with  $\text{Pb}(\text{OAc})_2$ ,  $\text{HgCl}_2$ ,  $\text{Fe}_2\text{Cl}_6$ , or  $\text{BaCl}_2$ . It reduces  $\text{AgNO}_3$  and Fehling's solution. By heating with acids it is converted into glucose.

**Salts.**— $\text{C}_{12}\text{H}_{22}\text{BaO}_{10} \cdot 3\text{aq}$ : white pp. formed by adding baryta to gallisin in aqueous alcoholic solution.— $\text{C}_{12}\text{H}_{22}\text{KO}_{10}$ : hygroscopic powder.— $\text{C}_{12}\text{H}_{22}\text{PbO}_{10} \cdot \text{PbO}$ : easily soluble white powder.

**Hexa-acetyl derivative**  $\text{C}_{12}\text{H}_6\text{O}_{16}(\text{OAc})_6$ : colourless glassy mass, insol. water, e. sol. alcohol, ether, benzene,  $\text{CS}_2$ , &c. (Schmitt a. Cobenzl, *B.* 17, 1000, 2456).

**GALLIUM Ga.** At. w. 69.9. Mol. w. unknown as V.D. of element has not been determined.  $[\alpha]_{\text{D}}^{20} = 28.5$ . S.G.  $\frac{700}{25}$  5.96 solid; 6.07 liquid. S.H. .079 solid; .0802 liquid. Latent heat of fusion = 1911 gram-units. Melted Ga remains liquid at temperatures considerably under the M.P., but solidifies by contact with a trace of solid Ga; other metals do not cause solidification. The metal crystallises in quadric octahedra. Characteristic lines in the emission-spectrum are 4170 and 4031; both lines have been reversed by Liveing and Dewar (*Pr.* 28, 471).

Gallium was discovered by Lecoq de Boisbaudran in August 1875 in *zinc-blende* from Pierrefitte (Hautes-Pyrénées); the observation of two violet lines in the spark-spectrum of this

blende led to the discovery of the new element. The properties of Ga were found to be those of the element *eka-aluminium* as predicted by Mendeleeff (*v. Chemical relations of Gallium*).

**References.**—The memoirs of Lecoq de Boisbaudran are contained in *C. R.* 81, 493, 1100; 82, 168, 1036, 1098; 83, 611, 636, 663, 824, 1044; 86, 756, 941, 1240; 93, 204, 329, 816; 94, 695, 1154, 1227, 1439, 1625; 95, 18, 157, 410, 503, 703, 1192, 1332; and with Jungfleisch in *C. R.* 86, 475, 577. There are also memoirs by Berthelot in *C. R.* 86, 786; Dupré, *C. R.* 86, 120; Mendeleeff, *C. R.* 81, 909; Nilson a. Pettersson, *C. R.* 91, 232. A general account of gallium is given by de Boisbaudran in Fremy's *Encyclopédie Chimique*, tome iii. cahier 5, pp. 202 *et seq.* [1881].

**Occurrence.**—In very small quantities in various zinc-blendes, and in many specimens of commercial zinc. The best source of the metal is the blende from Bensberg on the Rhine; de Boisbaudran and Jungfleisch obtained 52 grams of pure gallium from 4300 kilos. of this blende.

**Testing blendes for gallium.**—The blende is treated with *aqua regia*, the solution is heated to remove nitric acid; when cold, zinc (free from Ga) is added; various metals are thus ppd.; while H is still being evolved the liquid is poured through a filter; large excess of Zn is added, and the liquid is boiled until a white pp. forms; this pp. is collected, washed, and dissolved in  $\text{HClAq}$ ; the solution is concentrated to a small volume, and examined by causing a small induction-spark to play over the surface of the liquid, and passing the light through a spectroscope. 10 grams of a gallium-containing blende is sufficient to give the chief spectral lines of Ga.

**Preparation.**—1. The powdered blende is treated with *aqua regia*, excess of blende being always present in order to saturate the nitric acid; to the filtered liquid, when cold, Zn (free from Ga) is added; Sb, As, Bi, Cd, Cu, Au, In, Pb, Hg, Ag, Tl, Sn, and Se if present, are thus ppd.; while H is still coming off, the liquid is filtered; the filtrate is boiled with a large excess of Zn until a white pp. appears; this pp. contains all the Ga as hydrated oxide (or as a basic salt) mixed with  $\text{Al}_2\text{O}_3$ , basic salts of Fe, Zn, Cr, Co, and some  $\text{SiO}_2$ . The pp. is dissolved in  $\text{HClAq}$ , and  $\text{H}_2\text{S}$  is passed into the liquid; the pp. is removed by filtration;  $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2\text{Aq}$  or  $\text{NaC}_2\text{H}_3\text{O}_2\text{Aq}$ , and acetic acid are added to the filtrate, which is then ppd. by  $\text{H}_2\text{S}$ ; it is advisable to ppt. fractionally and to continue until the filtered liquid ceases to show Ga lines in the spectroscope; if the filtrate from the last batch of pp. shows the lines of Ga, a zinc salt must be added and the process of ppn. repeated. The pp. by  $\text{H}_2\text{S}$ , which contains all the Ga, is well washed and then dissolved in  $\text{HClAq}$ ; the Ga is then ppd. by one of the following methods: (1) the solution is boiled with as small an excess of Zn as suffices to ppt. the Ga; (2) the solution is boiled till  $\text{H}_2\text{S}$  is all off, and then fractionally ppd. by  $\text{NH}_4\text{Aq}$  or  $\text{NaOH Aq}$ ; (3)  $\text{H}_2\text{S}$  is removed, and Ga oxide is ppd. by addition of  $\text{BaCO}_3$  or  $\text{CaCO}_3$ . The crude Ga oxide obtained by one of these methods is washed and dissolved in  $\text{HClAq}$ ; some  $\text{Na}_2\text{SO}_4$  is added (to reduce  $\text{FeCl}_3$  to  $\text{FeCl}_2$ ), and the liquid is boiled for some time; excess of  $\text{CaCO}_3$  is then added, and the liquid is filtered as

once, as far as possible out of contact with air; this treatment is repeated twice; the greater part of the impurities is thus removed. The ppd. Ga oxide mixed with  $\text{CaCO}_3$  is dissolved in  $\text{HClAq}$ ;  $\text{NH}_4\text{Aq}$  is added in excess, and the liquid is boiled until it shows an acid reaction, water being added from time to time; the pp. is dissolved in  $\text{H}_2\text{SO}_4\text{Aq}$ , and the liquid is evaporated until white fumes come off; the last traces of chlorides are thus removed. To the sulphate is added considerable excess of pure  $\text{KOH}$  (free from chloride). After gentle warming the liquid is filtered (oxides of Fe and In are thus removed), and the strongly alkaline liquid is electrolysed, Pt electrodes are used, and the positive plate should be 6 to 10 times larger than the negative. The Ga is removed by the finger from the Pt plate under warm water, and allowed to stand for an hour or two in water acidulated with pure  $\text{HCl}$ , and then in dilute pure potash solution for a little at  $50^\circ\text{--}60^\circ$ ; it is then washed with water. 2. Iron may be used in place of zinc to effect the reduction of the solution of the blende; only a little Cd, Pb, &c., are thus ppd., so that the first filtration is omitted. The liquid containing Fe is boiled till a white pp. forms,  $\text{CaCO}_3$  in slight excess is added, and the liquid is filtered at once. The pp. is dissolved in  $\text{HClAq}$ , and the liquid is reppd. by  $\text{CaCO}_3$ ,  $\text{Na}_2\text{SO}_4$  being added to prevent oxidation of ferrous iron. Finally the pp. is dissolved in  $\text{HClAq}$ , and oxides of Cr and Al are removed by one of the following methods: (1) tartaric acid and a Mn salt are added, and then excess of  $\text{NH}_4\text{Aq}$ ; addition of  $\text{NH}_4$  sulphide then ppts.  $\text{MnS}$ , and with it all the Ga; this treatment is repeated two or three times; the pp. is then dissolved in  $\text{HClAq}$ , digested when cold with  $\text{CaCO}_3$ , and the ppd. Ga oxide mixed with  $\text{CaCO}_3$  is heated as directed in 1; (2)  $\text{K}_2\text{FeCy}_4$  is added to the solution in  $\text{HCl}$ ; the pp. is washed with water containing  $\frac{1}{4}$  to  $\frac{1}{2}$  its weight conc.  $\text{HClAq}$ ; the ferrocyanide pp. is then dried and fused with  $\text{KHSO}_4$ , and the fused mass is treated with water; to the solution excess of  $\text{NH}_4\text{Aq}$  is added, and it is then boiled for some time; the pp. is washed and dissolved in  $\text{HClAq}$ , and this liquid is treated with  $\text{Na}_2\text{SO}_4$  and  $\text{CaCO}_3$  as directed in 1.

**Properties.**—A grey metal, with greenish-blue reflection; fairly hard; crystallises in quadric octahedra; brittle, but may be hammered into thin plates, which can be bent without breaking. When melted, Ga is a silver-white liquid with faint reddish reflection. It melts at  $30\text{--}15^\circ$  and remains liquid nearly to  $2^\circ$ ; if a small piece of solid Ga is placed in the liquid metal below  $30\text{--}15^\circ$  the whole solidifies; metals other than Ga fail to produce solidification. According to J. Regnaud, liquid Ga is electronegative to solid Ga (*C. R.* 86, 1457). Ga is unchanged in air at boiling water. Heated in air to full redness it does not volatilise, and is oxidised only superficially. It is superficially oxidised when heated to redness in dry O. The atomic weight of Ga has been determined (1) by converting a known mass of the metal into oxide (De Boisbaudran, *C. R.* 86, 941); (2) by strongly heating gallium-ammonium alum (De B., *loc.*); (3) from determinations of the V.D. of  $\text{GaCl}_3$ ,  $\text{GaCl}$ , (Nilson a. Pettersson, *C. J. Trans.* 1888, 822); (4) by determining S.H. of Ga; (5) by establishing that

$\text{Ga-NH}_4$  sulphate is isomorphous with alum, and hence assigning a formula to the Ga compound (v. also *Chemical relations of Gallium*). As the chlorides  $\text{GaCl}_3$  and  $\text{GaCl}$  have both been gasified (Nilson a. Pettersson, *C. J. Trans.* 1888, 822) the atom of Ga appears to be both divalent and trivalent in gaseous molecules.

**Reactions.**—1. Heated to full redness in air, or oxygen, Ga is superficially oxidised.—2. Does not decompose water at  $100^\circ$ .—3. Dissolved slowly by hydrochloric acid with evolution of H. 4. Warm nitric acid dissolves Ga, forming nitrate.—5. Slowly dissolved by potash solution, also by ammonia.—6. Combines rapidly with chlorine at ordinary temperature, more slowly with bromine, and with iodine only when heated. 7. Alloys very easily with aluminium; the alloys decompose cold water rapidly.

**Separation and Estimation of Gallium;** v. De Boisbaudran, *C. R.* 93, 816; 94, 1154, 1227, 1439, 1625; 95, 157, 410, 503, 703, 1192, 1332.

**Chemical relations of Gallium.**—Gallium is the fourth member of Group III., in the grouping of the elements according to the periodic law. When Mendeleeff published his first extensive memoir on the periodic law, he was obliged to leave the positions III.-4 and III.-5 unfilled; none of the known elements could be placed in either of these places. Mendeleeff, however, predicted the properties of the elements which would be discovered to fill the vacancies. One of the two unknown elements was assigned a place in series 5. Now the differences between the values of the atomic weights of the elements in series 3 and 5, beginning with Group I. (and omitting Group III. as the unknown element we are considering is placed in that group) are, 40 in Group I., 41 in Group II., 44 in Group IV., 44 in Group V., 47 in Group VI., and 44.5 in Group VII. Hence, it was argued, the difference will be about 42 in Group III.; but the element in III.-3 is Al with at. w. 27; hence the unknown element in III.-5 will have an at. w. of about  $27 + 42 = 69$ . By tabulating the differences between the atomic weights of elements in series 4 and 5, of course omitting Group III., the following numbers are obtained; 24, 25, —, 24, 24, 27, 25. Hence in Group III. the difference will be about 25; but there was a gap in series 4 Group III., hence it was necessary first of all to calculate a value for the at. w. of the unknown element which ought to find a place in III.-4, and then to add 25 to this value. The result was that the element in III.-4 should have the at. w. 44; hence,  $44 + 25 = 69$ . Having thus determined the at. w. of the element which would be placed in III.-5 when it was discovered, Mendeleeff proceeded to determine the properties of this element by studying (1) the properties of the members of Group III., (2) the properties of the members of series 5, (3) the relations between Group III. as a whole and other groups, especially considering the position of the group in the complete scheme of classification, and (4) the relations of series 5 to other series. Group III. is on the whole composed of metals; the only decided non-metal is B; but B is succeeded by the metal Al. As the unknown element would come next but one to Al, and would be followed by Y, La, In, Yb, Tl, it would certainly be a metal, and would resemble Al generally. Then

considering that the unknown element would follow the metals Cu and Zn, in series 5, and would be followed by the element As which is both metallic and non-metallic, As being succeeded by the non-metals Se and Br, it might safely be asserted that the unknown element would be metallic, but probably less metallic than Cu and Zn. The composition and properties of the compounds of the Al group of elements determined the general composition and properties of the compounds of the unknown metal; it would form an oxide  $M_2O_3$ , a chloride  $M_2Cl_3$ , or  $MCl_3$ , it would form salts  $M_2SO_4$ ,  $M_2NO_3$ , &c. Then, considering the position of the element as regards Al, it was argued that the relations of this body, when discovered, to Al would be somewhat similar to those of Zn to Hg, or As to P, or Se to S. But as Zn is less like Hg than As is like P, and as As is less like P than Se is like S, it was concluded that the resemblance between the new element and Al would be fairly close, although not quite so marked as that between As and P, or Se and S; hence, it would probably form an alum. Guided by such reasoning as this, Mendelejeff was able to tabulate precisely the properties of the element which he placed in III.-5, and to which he gave the name of *eka-aluminium*. The properties of gallium were found to agree extremely closely with those of *eka-aluminium* (v. table in vol. i. p. 352).

Lecoq de Boisbaudran calculated the at. w. of Ga by comparing its spectrum with those of analogous elements, and comparing this result with the spectral relations of similar elements, the at. ws. of all of which were known. The at. ws. of the three similar elements K, Rb, Cs, show the following relations:—

	At. w.	Differences	
K. . .	39.1	46.26	1.38
Rb . .	85.36		
Cs . .	133	47.64	

The increase in at. w. from Rb to Cs = increase from K to Rb  $\times 1 + .02983$ . Then comparing the wave-lengths of the chief pairs of lines in the spectra of these three elements, we get this result:—

	Wave-lengths	Means	Differences
K . .	5831 } 5812 }	5821	
Rb . .	6297 } 6203 }	6250	170
Cs . .	6975 } 6723 }	6849	599

The increase in wave-length from Rb to Cs = increase from K to Rb  $\times 1 + .3963$ .

Turning now to the three elements of which Ga forms the middle member, we have:—

	At. w.	Differences
Al . . .	27.5	
Ga . . .	?	86.0
In . . .	113.5	

And tabulating the wave-lengths of the principal pairs of lines, we have:—

	Wave-lengths	Means	Differences
Al . .	8963 } 8944 }	8953	
Ga . .	4170 } 4031 }	4100	147
In . .	4511 } 4101 }	4306	206

The increase in the wave-length from Ga to In = increase from Al to Ga  $\times 1 + .4014$ . Then if it is assumed that the increase in wave-length ( $\lambda$ ) is related to the increase in atomic weight ( $a$ ) similarly in both sets of elements, we have the statement:—

$$\begin{aligned} \lambda K \text{ to Cs} : aK \text{ to Cs} &= \lambda Al \text{ to In} : aAl \text{ to In} \\ .3963 : .02983 &= .4014 : x \\ &\text{and } x = .030214. \end{aligned}$$

Now, putting the difference of at. w. between Al and Ga as  $A$ , the difference between Ga and In as  $B$ , we find that  $B = A(1 + .030214)$ ; and as  $A \times (2 + .030214) = 86$ , it follows that  $A = 42.86$  and  $B = 48.64$ ; hence the at. w. of Ga is found to be (1)  $27.5 + 42.86 = 69.86$ , and (2)  $113.5 - 48.64 = 69.86$ . The observed at. w. is 69.9.

For the properties of the elements of Group III., to which Ga belongs, v. EARTH, METALS OF THE, p. 424.

**Gallium bromides.** Ga and Br combine directly to form a colourless crystalline mass, which is less volatile than  $GaCl_3$ . Probably two bromides,  $GaBr_2$  and  $GaBr_3$ , are produced; but they require further investigation.

**Gallium chlorides.** Two are known,  $GaCl_2$  and  $GaCl_3$ . Both have been gasified.

**GALLIUM DICHLORIDE**  $GaCl_2$ . Mol. w. 140.64. V.D. at  $1000^\circ - 1400^\circ$  60.6 (Nilson a. Pettersson, C. J. 53, 825). Prepared by heating Ga in  $Cl_2$ , keeping the metal in excess; or better, by heating  $GaCl_3$  with Ga for a long time, and then distilling in dry  $CO_2$  (N. a. P., l.c.). White transparent crystals, melting at  $104^\circ$ , and boiling at c.  $535^\circ$ . When melted it may be kept for a long time without solidifying. Vapour fumes in the air. Deliquesces in moist air to a clear liquid; addition of water causes ppn. of a grey solid (? oxychloride or suboxide, or  $GaCl$  v. N. a. P., l.c.), and evolution of H. Solution of  $GaCl_2$  in  $HCl$  aq. reduces  $KMnO_4$  aq. At a white heat  $GaCl_2$  appears to decompose into Cl and a lower chloride (N. a. P., l.c.).

**GALLIUM TRICHLORIDE**  $GaCl_3$ . Mol. w. 176.01. V.D.  $440^\circ$  to c.  $1000^\circ$  89; at  $350^\circ$  V.D. = 128 (Nilson a. Pettersson, C. J. 53, 824). V.D.  $237^\circ - 307^\circ$  161.6; at  $377.6^\circ$  V.D. = 113.2 (Friedel a. Crafts, C. R. 107, 306). These results point to the existence of  $Ga_2Cl_6$  at c.  $250^\circ$ , and to the gradual dissociation of this molecule into  $GaCl_3$ . S.G.  $80^\circ$  2.36.

$GaCl_3$  may be prepared by heating Ga in excess of  $Cl_2$  and distilling the product in N, or by heating Ga in dry  $HCl$  gas free from air. It forms long white needles, which melt at  $75.5^\circ$  and boil at c.  $215^\circ - 220^\circ$ . When melted it remains liquid at temperatures below its m.p.

Molten  $GaCl_3$  absorbs gases readily, e.g. N and Cl, and gives them off again on crystallising. It is deliquescent in moist air; dissolves in water with production of much heat. When this solution is evaporated an amorphous mass is obtained, which absorbs moisture and becomes gelatinous. When this gelatinous substance was kept in closed tubes for several years small crystals were obtained having the composition  $Ga_2Cl_6 \cdot Ga_2O_3 \cdot 18H_2O$  (L. de B.). At about  $1100^\circ$   $GaCl_3$  begins to decompose into  $GaCl$  and Cl (N. a. P., l.c.).

**Gallium ferrocyanide** is ppd. as a white salt by adding  $K_4FeCy_6$  to solution of  $GaCl_3$ . Composition not determined.

**Gallium iodides.** Two probably exist, corresponding with the two chlorides; but they have not been thoroughly investigated. Ga and I combine when heated together.

**Gallium oxides.** Two probably exist.

**GALLIUM MONOXIDE** ( $? GaO$ ) is probably formed by heating  $Ga_2O_3$  to redness in a stream of H. The substance thus formed is a greyish-blue mass, which dissolves in  $HNO_3$  and in dilute  $HClAq$ ; the solution in  $HClAq$  decolourises  $KMnO_4$ .

**GALLIUM SESQUIOXIDE**  $Ga_2O_3$ . White solid, formed by heating  $Ga_3NO_3$ . Dissolves in acids to form Ga salts. Does not melt at white heat. Reduced to Ga by H at a high temperature. S.H. 1062. Hydrated gallium oxide ( $? GaO_3H_2$ ) is ppd. from solutions of Ga salts by carbonates and bicarbonates of the alkalis. It is sol. in excess of the pptant., more sol.  $NH_4Aq$  and  $(NH_4)_2CO_3Aq$ , and v. sol.  $KOHAq$ .

**Gallium salts of.** Only a few salts have been prepared. The chief are  $Ga_3NO_3$ , and  $Ga_2SSO_4$  (v. NITRATES and SULPHATES). They are obtained by dissolving  $Ga_2O_3$  in acids and evaporating. The sulphate forms an ammonia-alum  $Ga_2SSO_4 \cdot (NH_4)_2SO_4 \cdot 24H_2O$ .

**Sulphydic acid** does not ppt. Ga salts. If, however, the solution is alkaline, or is acidified by a weak acid, and a metal is present whose salts are ppd. by  $H_2S$ , e.g. Zn, then the Ga is also ppd. **Potash** ppts. Ga salts; the pp. is e. sol. in excess of the pptant. **Potassium ferrocyanide** gives a pp. with so little as  $\frac{175,000}{100,000}$  part of a Ga salt in an HCl solution. **Barium carbonate** ppts.  $Ga_2O_3$  in the cold. **Zinc** does not ppt. Ga from acid solutions; but as soon as the acid has been neutralised by the Zn white flocks of  $Ga_2O_3$ , ppt.

**Gallium sulphide.** The white pp. obtained by passing  $H_2S$  into a conc. solution of  $GaCl_3$  in  $NH_4Aq$ , to which  $NH_4$  tartrate has been added, is probably a sulphide of Ga. M. M. P. M.

**GALLOCARBOXYLIC ACID** v. PYROGALLIC-DICARBOXYLIC ACID.

**GALLOCYANINE**  $C_8H_8N_2O_6$ . Formed by heating gallic acid and the hydrochloride of nitroso-dimethyl-aniline in an alcoholic or HOAc solution (Nietzki & Otto, B. 21, 1740; cf. Pabst, Bl. [2] 38, 162; Köchlin, C. N. 47, 170). Shiny green needles, almost insol. water, alcohol, and HOAc. Sol. alkalis with reddish colour. Conc. acids dissolve it with reddish-violet colour. The salts so formed are decomposed by water. Dyes wool, mordanted with chromium, bluish-violet. **Anilide**  $C_7H_7N_2O_6$ . Lustrous green needles.

**Methyl ether**  $C_{11}H_{11}N_2O_5Me$ . 'Prune.' Formed by the action of nitroso-dimethyl-aniline hydrochloride on the methyl ether of gallic acid. Is more basic than galloxyanine and forms a crystalline hydrochloride. Dyes cotton, mordanted with tannin, or wool or cotton mordanted with chromium, bluish-violet.

**Di-acetyl derivatives** of the methyl ether  $C_{11}H_{11}N_2O_5MeAc_2$ . Small greenish needles (from alcohol).

**GALLOFLAVIN**  $C_{12}H_8O_4$ . Obtained by dissolving gallic acid (50 g.) in alcohol (375 c.c.) and water (1000 c.c.), cooling to  $0^\circ$ , adding 135 c.c. of 23 p.c. aqueous KOH, and passing air through the solution (Bohn & Graebe, B. 20, 2327). Greenish-yellow plates, sl. sol. water, alcohol, and ether. Dissolves in alkalis and their carbonates forming yellow solutions. Dyes wool, mordanted with chromium, yellow.  $-C_{12}H_8K_2O_4$ ; greenish-yellow crystals, v. sl. sol. cold water; boiling water liberates free galloflavin.

**Acetyl derivative**  $C_{12}H_8Ac_2O_4$ . [230°]. White needles, v. sol. HOAc.

**Chloro-acetyl derivative**

$C_{12}H_8(C_2H_3ClO)_2O_4$ . [212°].

**GALLOL**  $C_{12}H_{10}O_4$ , i.e.

$O < \begin{matrix} C_6H_7(OH)_2 \\ C_6H_7(OH) \end{matrix} > CH_2O.C_6H_7.CH_2.OH$ . Formed by reducing gallean (*q. v.*) with zinc-dust and dilute  $H_2SO_4$  (Baeyer, B. 4, 556; Buchka, A. 209, 264). Crystals, changing in the air to a reddish powder. Sl. sol. cold water and ether, v. e. sol. alcohol.

**Penta-acetyl derivative**  $C_{20}H_4Ac_5O_9$ . [230°].

**GAMBOGE.** A gum-resin which appears to be produced from *Stalagmites cambogioides*, a tree growing in Siam. It contains about 72 p.c. resin and 20 p.c. gum. Its powder is yellow. It is a drastic purgative. It dissolves in alcohol and ammonia; the ammoniacal solution gives a red pp. with  $BaCl_2$ , and yellow pps. with  $ZnSO_4$ , with lead salts, and with  $AgNO_3$ . Ether extracts a red resin which forms a yellow powder; it decomposes boiling alkaline carbonates forming red salts (Buchner, A. 45, 94; Christison, A. 76, 344; Costelo, Ph. [3] 9, 1022). Potash-fusion gives phloroglucin, acetic acid, isosuccinic acid  $C_6H_4O_4$ , and pyrotartaric acid (Hlasiwetz & Barth, A. 138, 61).

**GARDENIN**  $C_{11}H_8O_4$ . [164°]. Extracted from 'dekamali,' a resin from *Gardenia lucida*. After removing the volatile oil by distilling with steam, the residue is extracted with weak spirit, from which gardenin crystallises on cooling. It may be purified by successive crystallisation from benzene and petroleum spirit (Stenhouse & Groves, C. J. 31, 551; 35, 689; cf. Flückiger, Ph. [3] 7, 589). Deep yellow crystals. Almost insol. water, m. sol. alcohol. Insol. alkalis, sol. hot  $HClAq$ . Its solution in HOAc (30 pts.) treated with  $HNO_3$  (S.G. 1.45) gives gardenic acid.

**Gardenic acid**  $C_{11}H_8O_4$ ? [c. 228°]. Deep crimson needles, insol. water, light petroleum,  $CS_2$ , and almost insol. ether and benzene. Sol. alkalis.

**Acetyl derivative**  $C_{11}H_8Ac_2O_4$ . [244°]. Formed by the action of glacial acetic acid. Insol. water, light petroleum, and  $CS_2$ . Almost insol. ether and benzene. Sol. alkalis.

**Hydrogardenic acid**  $C_{11}H_8O_4$ . [190°]. Formed by the action of  $H_2SO_4$  on gardenic acid. Flat needles. May be re-oxidised to gardenic acid.

**GARLIC OIL.** Contains allyl sulphocyanide (Wertheim, A. 51, 289) and a sesquiterpene  $C_{15}H_{22}$  (254°) (Beckett & Wright, C. J. 29, 1).

**GARRYNE.** A substance crystallising in cubes and occurring in the leaves and roots of *Garrya Fremontii*. It is sol. water and alcohol.

and gives a purple colour with  $\text{H}_2\text{SO}_4$  (Ross, *Ph.* [3], 8, 489).

**GASES, ABSORPTION OF.** The more important chemical aspects of the absorption of gases are treated in the article DISSOCIATION; v. especially pp. 395-399.

**GASES, ANALYSIS OF, v. ANALYSIS, vol. i.** pp. 252-247.

**GASES, COMBINATION OF, BY VOLUME,**

v. COMBINATION, CHEMICAL, LAWS OF, pp. 236, 238.

**GASES, DIFFUSION OF, v. DIFFUSION,** p. 284; and also PHYSICAL METHODS.

**GASES, TRANSPIRATION OF.** The rate of flow of gases through capillary tubes is generally called the transpiration of gases. Measurements of *transpiration-constants* are more important in physical than in chemical inquiries.

**GAISPEINE**, a misprint for GALIPEINE.

**GAULTHERIA OIL**, or *Oil of Wintergreen*, is obtained from the leaves of *Gaultheria procumbens*, growing in New Jersey, by steam distillation. It consists of methyl salicylate ( $222^\circ$ ) mixed with a small quantity of a terpene  $\text{C}_{10}\text{H}_{16}$  ( $160^\circ$ ). V.D. 4-92 (Cahours, *A. Ch.* [3] 10, 327; Procter, *J. Ph.* [3] 3, 275; A. 48, 66; Biedermann, *B. 8*, 1677).

**GEISSOSPERMINE**  $\text{C}_{19}\text{H}_{32}\text{N}_2\text{O}_2$ . [ $160^\circ$ ].  $[\alpha]_D = -93.4^\circ$  in a 1.5 p.c. solution at  $15^\circ$ . An alkaloid occurring in the Pereira bark (Hesse, *A.* 202, 143; B. 10, 2162). Small white prisms (containing aq.), sol. dilute acids but reppd. on neutralisation. Sl. sol. ether. Forms a purple solution in conc.  $\text{HNO}_3$ . It does not reduce  $\text{H}_2\text{PtCl}_6$  (Wulfsberg, *Ph.* [3] 11, 269). It gives pps. with  $\text{H}_2\text{Cl}_2$ , with  $\text{K}_2\text{Cr}_2\text{O}_7$ , with potassium-mercuric iodide, and with potassium picrate.

**Salts.**— $\text{B}^+\text{H}_2\text{H}_2\text{PtCl}_6$ : yellow flocculent pp.—**Aurochloride**: brown amorphous pp.—**Oxalate**: minute needles.—**Sulphate**: white needles.

**GELATIN v. PROTEINS, Appendix C.**

**GELOSE**  $\text{C}_6\text{H}_{10}\text{O}_2$ . Forms the essential constituent of China moss or Hai-Thao (Payen, *C. R.* 49, 521; Morin, *C. R.* 90, 924). Used for finishing cotton goods (Heilmann, *D. F. J.* 213, 522). When dissolved even in 500 times its weight of water it forms a jelly on cooling. After drying it is insol. cold water, alcohol, ether, weak alkalis or acids, and Schweizer's solution. Dilute  $\text{HNO}_3$  oxidises it to mucic acid. Its aqueous solution is ppd. by alcohol. Dilute  $\text{HCl}$ , acetic acid, and oxalic acid deprive it of its property of gelatinising; heating with water under 6 atmospheres' pressure has a like effect. A 10 p.c. aqueous solution is levorotatory,  $[\alpha] = -4^\circ 15'$ ; but boiling acidulated water slowly changes this to a nearly equal dextrorotation, the resulting solution reducing Fehling's solution, and being no longer ppd. by alcohol. By treating gelose with water at  $100^\circ$  Porumbaru (*C. R.* 90, 1061) got a levorotatory sugar  $\text{C}_6\text{H}_{12}\text{O}_6$  aq.

**GELSEMINE**  $\text{C}_{15}\text{H}_{25}\text{N}_2\text{O}_2$ . S. (ether) 4. May be extracted by alcohol from the root of *Gelsemium sempervirens* (Wormley, *Ph.* [3] 13, 106; Gerrard, *Ph.* [3] 13, 602, 641; Robbins, *B.* 9, 1182; Thompson, *Ph.* [3] 17, 803). Amorphous solid, melting below  $100^\circ$ . Sl. sol. water, m. sol. alcohol, v. sol. ether and chloroform. Its solution has a bitter taste and is strongly alkaline. It is very poisonous, producing con-

vulsions. Its hydrochloride is ppd. by the usual reagents for alkaloids. Conc.  $\text{H}_2\text{SO}_4$  gives a greenish-yellow solution soon turning reddish-brown; on adding  $\text{K}_2\text{Cr}_2\text{O}_7$ , a cherry-red colour turning to bluish-green appears.  $\text{HNO}_3$  turns it green.

**Salts.**— $\text{B}^+\text{HCl}$ : amorphous.— $\text{B}^+\text{H}_2\text{H}_2\text{PtCl}_6$ : amorphous. Using the formula  $\text{C}_{15}\text{H}_{25}\text{N}_2\text{O}_2$ , Thompson describes the salts  $\text{B}^+\text{H}_2\text{H}_2\text{Cl}_2$ ,  $\text{B}^+(\text{H}_2\text{AuCl}_4)_2$ , and  $\text{B}^+(\text{H}_2\text{PtCl}_6)_2$ .

**Gelseminine**. A resinous alkaloid which, according to Thompson, accompanies gelsemine.

**Gelsemic acid**. An acid which, according to Wormley, occurs in *Gelsemium sempervirens* and may be extracted by ether from the acidulated root. It dissolves in 2,912 pts. of water and in 330 pts. of ether.  $\text{HNO}_3$  turns it yellow, the solution becoming deep red on addition of ammonia. Gelsemic acid forms fluorescent solutions and is perhaps identical with asculin.

**TERGENIC ACID v. ETHYLIDENE-BURET.**

**GENTIANIN**  $\text{C}_{17}\text{H}_{25}\text{O}_5$  i.e.

$\text{C}_6\text{H}_4(\text{OH})_2\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{MeO}_2$ . *Gentisin*. *Gentianic acid*. The colouring matter of the root of *Gentiana lutea* growing in Switzerland and the Tyrol and used as a tonic (Henry a. Caventon, *J. Ph.* 7, 173; Baunert, *A.* 62, 106; Trommsdorff, *A.* 21, 134; Leconte, *A.* 25, 202; Hasiwetz a. Habermann, *B.* 7, 652; A. 175, 63; 180, 348). Pale-yellow needles, v. sl. sol. water, m. sol. ether, v. sol. boiling alcohol. Neutral to litmus. Alkalis dissolve it, yielding a deep golden solution. Between  $300^\circ$  and  $340^\circ$  it may be partially sublimed, but the greater part is carbonised. It is not attacked by dilute acids. Conc.  $\text{H}_2\text{SO}_4$  forms a yellow solution.  $\text{HNO}_3$  (S.G. 1.43) forms a green solution from which water throws down green  $\text{C}_{17}\text{H}_{25}(\text{NO}_2)_2\text{O}_5$  aq. Fuming  $\text{HNO}_3$  appears to form  $\text{C}_{17}\text{H}_{25}(\text{NO}_3)_2\text{O}_5$ . Potash-fusion splits up gentianin into phloroglucin, gentisic acid, and acetic acid. Gentianin reduces  $\text{AgNO}_3$ . Sodium-amalgam forms  $\text{C}_{17}\text{H}_{25}\text{O}_5$ , an amorphous red body.

**Salts.**— $\text{KHA}^+\text{aq.} - \text{KHA}^+ 2\text{aq.}$ — $\text{KHA}^+ 17\text{aq.} - \text{NaHA}^+ 2\text{aq.}$ : golden needles.— $\text{NaHA}^+ \text{aq.} - \text{NaHA}^+ 2\text{aq.}$ — $\text{BaA}^+ \text{aq.} - \text{PbA}^+\text{Pb}(\text{OH})_2$ .

**Acetyl derivative**  $\text{C}_{17}\text{H}_{25}\text{AcO}_5$ . [ $196^\circ$ ]. Slender crystals (from alcohol).

**GENTIANOSE**  $\text{C}_{17}\text{H}_{25}\text{O}_{10}$ . [ $210^\circ$ ]. Prepared from the juice of *Gentiana lutea* (taken in September) by exhausting with alcohol (95 p.c.) and fractionally ppd. with ether (A. Meyer, *H. 6*, 135). Colourless tables with sweet taste. Sol. water. Its aqueous solution is fermented by yeast. It is charred by  $\text{H}_2\text{SO}_4$ . It does not reduce Fehling's solution. It is dextrorotatory.

**GENTIOPICRIN**  $\text{C}_{17}\text{H}_{25}\text{O}_{10}$ . [ $121^\circ - 126^\circ$ ]. Occurs in the root of *Gentiana lutea* (Kromayer, *Ar. Ph.* [2] 110, 27). Needles; v. sol. water, sl. sol. alcohol, insol. ether; tastes bitter. Reduces hot ammoniacal  $\text{AgNO}_3$ . Does not reduce Fehling's solution. Split up by dilute acids into amorphous gentogenin  $\text{C}_{11}\text{H}_{19}\text{O}_5$  and a fermentable sugar.

**GENTISIC ACID v. DI-ORT-BENZOIC ACID.**

**GENTISIC ALDEHYDE v. DI-ORT-BENZOIC ALDEHYDE.**

**GENTISIN v. GENTIANIN.**

**GEOLOGICAL CHEMISTRY.** Since geology is a science which deals primarily with the con-

stitution and history of the earth, it is evident that there must be many points at which it comes into relation, directly or indirectly, with chemistry. Much of geological science is devoted to the study of rocks, or those large masses of mineral matter which build up the crust of the earth. The chemist is of service to the geologist not only in analysing these rocks, or the mineral species of which they are composed, but in explaining some of the processes by which the rocks themselves may have been originally formed, and in tracing the nature of the alterations to which they have been subjected since their formation. Hence the geological chemist gives special attention to those natural processes of rock formation in which chemical reactions are involved, and he endeavours to imitate the operations of nature by experiment in the laboratory. The experimental method was first introduced into geology by Sir James Hall, of Dunglass, who, in order to explain the origin of certain crystalline limestones, subjected pounded chalk to a high temperature in closed gun-barrels, and obtained, under certain conditions, a crystalline mass of carbonate of calcium somewhat resembling a saccharoidal marble (*T. E.* 6, 101, 121). It must be remembered, however, that much of the experimental work recorded in the literature of chemical geology refers to the synthesis of minerals rather than of rocks. A rock may, it is true, be composed of only a single mineral, but in most cases a rock is an aggregate of several distinct mineral species, and although the synthesis of each constituent may be successfully effected, it by no means follows that this work will throw light upon the origin of the composite rock. (For an excellent account of the present condition of mineral synthesis, see M. L. Bourgeois, *Reproduction artificielle des minéraux*, in Frey's *Encyc. Ch.* 1884; and Fouqué and Lévy's *Synthèse des Minéraux et des Roches*, Paris, 1882.)

**Analysis of Rocks.**—The simplest method is of course to analyse the rock as a whole, and in the case of a very fine-grained rock in which it is impossible to separate the mineral constituents individually, this is the only available method. The interpretation of the results of such an analysis requires, however, considerable sagacity, more especially if the constitution of the rock be complex. Two rocks, distinct in composition, such as a granite and a trachyte, may give the same bulk-analysis, while two rocks of similar mineral composition may yield different analyses. When the oxygen ratio, or quantivalent ratio, of a rock is known, as also that of each of its mineral components, it may be possible to calculate the percentage of each mineral in the rock (*v. S. Houghton, Quart. Journ. Geol. Soc.* 18, 418).

Methods of *fractional analysis* have been introduced for the purpose of effecting a chemical separation of the constituents of certain rocks. Gmelin, in his analyses of phonolites, was perhaps the first to separate the part soluble in hydrochloric acid from that which was insoluble, and to analyse each separately. Grave objections may, however, be urged against this method, and it is now rarely used. More trustworthy results have been obtained by treating the rock, if composed of various silicates, with hydrofluoric acid,

which attacks the several minerals in unequal degree. Such a method is sometimes useful in controlling a bulk-analysis.

Of late years considerable use has been made of certain dense liquids for the purpose of effecting the mechanical separation of the minerals which compose a rock, in order that each constituent may be isolated in a state of purity for separate analysis. The S.G. of the liquid is so adjusted that when the rock is coarsely powdered and thrown into the liquid certain of the minerals float while others sink. Several such liquids are now in common use in the geological laboratory (*v. J. W. Judd, Proc. Geol. Assoc.* 8, 278; and F. Rutley, *Rock-forming Minerals*, London, 1888).

Sonstadt's solution, recommended by Church, consists of a solution of HgI<sub>2</sub> and KI; it may be obtained with S.G. 3.196 (*C. N.* 29, 127; *Neues Jahrb. f. Min., Beilage* 1, 179). It is also known as Thoulet's solution. If a rock consisted of plagioclase with S.G. 2.7 and augite with S.G. 3.1, and these minerals were set free by mechanical disintegration of the rock, a complete separation might readily be effected in Sonstadt's solution with S.G. of about 3. The poisonous and corrosive character of the solution, however, tends to limit its use. Klein's solution is a boro-tungstate of cadmium, less dangerous than Sonstadt's, and capable of attaining to a higher S.G., the maximum being about 3.6. The solution has, however, the disadvantage of being decomposed by carbonates, and therefore if these be present in the rock they should be removed before the solution is used (*Bull. Soc. Min. France*, 4, 149). Rohrbach's solution resembles Sonstadt's, but contains BaI<sub>2</sub> in place of KI; its maximum S.G. is 3.68. It is unfortunately decomposed in the presence of water, so that all minerals used must be perfectly dried (*Neues Jahrb.* 11, 186). Brauns has recommended the use of methyl iodide, which has S.G. 3.337 at 10°. Bréon advocates the employment of fused PbCl<sub>2</sub>, either alone or mixed with ZnCl<sub>2</sub>; but though by properly adjusting the proportions of the constituents it may be prepared of high S.G., its use in a state of fusion is attended with much inconvenience (*Bull. Soc. Min. France*, 3, 46).

The S.G. of a heavy solution may be conveniently determined by means of Westphal's hydro-balance (*Neues Jahrb. f. Min.* 2, 87). The S.G. of very small fragments of minerals and rocks may thus be accurately taken: the fragments are placed in the dense solution, which is then diluted until they remain suspended indifferently in any part of the liquid (*v. also W. J. Sollas, Proc. R. Dublin Soc.*, Jan. 19, 1885). The separation of one mineral from another, when in small particles, is best effected in a special type of separating funnel, devised by Harada and improved by Brögger. (For the subject generally *v. Rosenbusch, Mikroskop. Physiol.* 2 Aufl. Bd. i. [Stuttgart], 1885, pp. 194, 215; English translation by Iddings, 1888, p. 91.)

The mechanical separation of the constituent minerals of a rock, previous to chemical analysis, is aided by the use of a powerful magnet. With an electro-magnet of great power, silicates rich in iron, such as hornblende, augite, and biotite,

may be picked out of the pulverised rock (Fouqué a. Lévy, *Min. Micrograph.* (Paris, 1879), 116). (For a large collection of analyses of rocks consult J. Roth, *Die Gesteins-Analysen* (Berlin, 1861), and his *Beiträge*, 1873-84.)

*Micro-chemical examination of rocks.*—The microscopic examination of thin sections of rocks, which forms an important branch of modern petrography, has led to the introduction in recent years of certain micro-chemical tests for distinguishing one mineral species from another. The micro-chemical methods do not aim at effecting a complete analysis of the microscopic constituents of a rock, but are used rather for the purpose of controlling optical determinations.

The rock may be coarsely powdered in a steel mortar, and the particles to be examined after separation of the fine powder by a sieve may be picked out by aid of the forceps, or if too small may be removed on the point of a needle moistened with glycerine, from which the accumulated grains may be detached by dipping the needle into water. Any steel particles derived from the mortar may be separated by a magnet. In other cases the constituent minerals are so minute that it becomes necessary to prepare a thin section of the rock and subject it to examination under the microscope. By means of a needle, the grains to be examined may be picked out from the section. It is convenient for the operator to commence by detaching the fragments near the edge, and to work patiently thence towards the centre of the section. The section is, of course, not protected by a cover-glass; and the Canada balsam by which the slice is cemented to the glass is dissolved off by treatment with alcohol.

In some cases the particles to be examined cannot conveniently be separated, and it then becomes necessary to attack the mineral in the section itself. The particular mineral to be tested is brought into the field of the microscope, and a perforated cover-glass is then drawn over the section in such a way that the mineral is just under the perforation. Through this aperture the balsam is dissolved, and the mineral exposed ready for attack by the reagent. If hydrofluoric acid is to be used the section is covered with a perforated slip of platinum foil instead of a cover-glass. By means of a pipette a drop of the solvent is lodged on the slide, and the liquid may then be conducted to the mineral exposed at the aperture by the point of a platinum wire.

The general method in these micro-chemical reactions is to produce certain compounds which present distinctive crystalline forms capable of recognition under the microscope. In Boricky's method the microscopic minerals are attacked with  $\text{H}_2\text{SiF}_6\text{Aq}$ , which forms a series of crystallised silicofluorides, many of which are sufficiently characteristic in form to be readily recognised. Uncertainty is, however, introduced by the fact that several of the silicofluorides are isomorphous. Behrens attacks the rock with  $\text{HFAq}$ , and treats the product with  $\text{H}_2\text{SO}_4\text{Aq}$ . In Streng's processes most of the salts crystallise out as chlorides. For the special reactions, and for figures of the microscopic crystals produced by these reactions, reference may be made to Klement a. Benard, *Réactions Microchimiques*, Brussels, 1886; Haushofer, *Mikroskopische Reactionen*, Munich, 1885;

Behrens, *Mikrochemische Methoden zur Mineralanalyse*, Vers. en Med. d. k. Ak. Wetensch., Amsterdam, 1882; and G. Boricky, *Éléments einer neuen chem.-mik. Min.- u. Gesteinsanalyse*, Aroh. d. naturw. Landesfor. v. Böhmen, Prague, 1877.

The geological chemist is often called upon to decide the nature of a given felspar in a rock, and for this purpose the method introduced by Szabó of Budapest is convenient. An extremely small particle of felspar is introduced into the flame of a Bunsen burner provided with a special chimney of sheet-iron. The proportion of soda or potash may be approximately determined by comparing the extent of the yellow or red colouration with the standard plates issued by Szabó. In experienced hands this process yields remarkably precise results (v. Szabó, *Ueber eine neue Methode, die Feldspathe in Gesteinen zu bestimmen*, Budapest, 1876; and F. Rutley, *Rock-forming Minerals*, London, 1888, p. 9).

*Classification of Rocks.*—Some rocks have evidently been formed as deposits in a watery medium, while others have existed at some period at a high temperature and been more or less completely fused; hence arise two great groups of rocks: one of *aqueous*, the other of *igneous*, origin. Certain rocks, whether aqueous or igneous, have suffered such alteration since their formation that their original characters are no longer to be recognised by direct observation, and hence these are known as *metamorphic* rocks. Of the so-called aqueous rocks a few have been deposited directly from solution as chemical precipitates; but by far the larger number have been thrown down as sediments from a state of mechanical suspension. The aqueous deposits are known as *sedimentary* or *stratified* rocks, while the igneous rocks are often described as *unstratified* or *massive*. In addition to these types there are a few rocks, like coal and certain limestones, which owe their origin, directly or indirectly, to organic agencies, and are hence termed *organic* rocks. But though the ultimate origin of such deposits is organic, the changes through which they have passed in reaching their present condition are essentially chemical.

It usually happens that several modes of formation have contributed to the production of a single rock. Thus, rocks formed as chemical precipitates, though practically homogeneous, may contain an admixture of foreign matter representing material that was mechanically thrown down during precipitation. On the other hand, a sedimentary rock frequently has its constituent grains bound together by mineral matter which has been precipitated in association with, or subsequent to, the mechanical deposit, and has acted as a cementing medium; a sandstone, for example, may have its component grains united by mineral matter precipitated from solutions percolating through the original mass of sand. (On the origin and classification of rocks, consult A. Geikie, *Text-book of Geology*, 2nd ed., 1885; A. H. Green, *Physical Geology*, vol. i., 3rd ed., 1882; J. J. H. Teall, *British Petrography*, 1888; A. de Lapparent, *Traité de Géologie*, 2nd ed., Paris, 1885; and H. Credner, *Elemente de Géologie*, Leipzig, 3rd ed., 1876.)

In dealing with igneous rocks it is always

desirable to ascertain the proportion of silica in the rock as a whole, since a common classification of such rocks is based upon this datum. Bunsen, in studying the rocks of Iceland, suggested that all igneous rocks have been formed by admixture of two magmas which he termed the *normal trachytic* and *normal pyroxenic* (P. 83, 197). Durocher afterwards developed a theory which derived the rocks from two magmas situated at different subterranean depths, termed by him *acid* and *basic*, and practically corresponding respectively with the trachytic and pyroxenic magmas of Bunsen (Durocher, *Essai de Pétrologie comparée*, Ann. de Mines, 40, 1857, pp. 217, 676). At the present time most petrographers define the *acid* or *light* rocks as those containing from 65 to 80 p.c. of silica, and having S.G. 2.3 to 2.7; they usually contain a high proportion of alkalis, especially potash, and but a small percentage of lime, magnesia, and oxides of iron. On the other hand, the *basic* or *dense* rocks contain only from 45 to 55 p.c. of silica, but have S.G. rising from 2.5 to as high as 3.1; they are characterised by a low percentage of alkalis, with more soda than potash, and by a high percentage of lime, magnesia, and oxides of iron (v. Teall, *Brit. Pet.*, cap. ii.; and on the classification of igneous rocks, Bonney's anniversary address, *Geol. Soc.*, 41, 1885).

**Chemically-formed Rocks.**—The chemical precipitates which are of interest to geologists, as having been formed on a large scale in nature, belong chiefly to the groups of carbonates, sulphates, and chlorides, represented respectively by such rocks as limestone, gypsum, and rock-salt. Perhaps the simplest example is offered by *rock-salt*, since this has been formed by the mere evaporation of a natural brine. On the composition of sea-water—a subject of much interest to the geological chemist—v. Dittmar, *Rep. of Challenger*, 1884; Forchhammer, T. 155, 203; J. Roth, *Allgemeine u. Chemische Geolog.*, Bd. 1 (Berlin, 1879); and Bischof, *Chem. u. Phys. Geolog.*, 2nd ed., Bd. 1 [Bonn, 1863], p. 426.

Rock-salt has usually been formed in inland sheets of salt-water. These are either isolated portions of the sea or the relics of lakes which were originally fresh but have acquired salinity by the accumulation of salts introduced by river-waters. The great Salt Lake of Utah, situated in an area of inland drainage, receives streams which bring in salt; but, having no outlet, the waters tend to become concentrated. In this arid region evaporation is rapid, and along the shallow margin of the lake vast quantities of common salt spontaneously crystallise during the dry season; while in winter, whenever the temperature falls below  $-6.5^{\circ}$   $\text{Na}_2\text{SO}_4$  is ppd., the quantity of this salt formed in a single season amounting to thousands of tons. Many ancient lakes have in the course of time completely disappeared by desiccation, and their position is now marked by extensive saline deposits. For the chemical history of a fossil lake, see J. C. Russell's "Lake Lahontan" in *Memoirs of U. S. Geol. Surv.* 1885.

On the evaporation of a salt-lake, or saline lagoon, the least soluble salts will tend to crystallise first, the order in which the salts are successively deposited being inversely as the order

of their solubility. Such a process of fractional crystallisation in nature is illustrated by the remarkable salt-deposits at Stassfurt in Prussia. In the lowest beds the rock-salt is associated with gypsum, anhydrite, and carbonate of calcium; but above the rock-salt there are deposits of deliquescent compounds, rich in potassium and magnesium, which remained in the mother-liquor after the NaCl had separated. The association of the rock-salt and anhydrite in alternate layers has led to the suggestion that they represent seasonal deposits, the former having been deposited in the warmer, and the latter in the colder, parts of the year. The soluble salts above the main mass of rock-salt, known locally as *Abramssalze*, consist chiefly of polyhalite ( $\text{K}_2\text{SO}_4 \cdot \text{MgSO}_4 \cdot 2\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), kieserite ( $\text{MgSO}_4 \cdot \text{H}_2\text{O}$ ), and vernallite ( $\text{KCl} \cdot \text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ ); v. Bischof, *Die Steinsalz bei Stassfurt*, 2 Aufl. 1875; Oehsenius, *Die Bildung der Steinsalzlagen*, 1877; Precht, *Die Salzindustrie von Stassfurt*; Bauerman, *Proc. Civil Eng.* 88, 415; and C. Napier Hake, *S. C. I.*

**Origin of Limestone.**—One of the commonest examples of a chemically-formed rock is afforded by certain deposits of *limestone* which have been ppd. from calcareous waters. Such are the deposits known as *calcareous sinter* or *tufa*, so commonly formed by springs flowing through limestone districts, and forming in some cases important rock-masses, like the *travertine*, or 'Tibur stone,' of Tuscany. But while certain limestones are the result of direct ppn., it appears that by far the greater number of such rocks owe their origin to organic agencies. Such, for instance, is the chalk which is largely made up of the calcareous tests of foraminifera; such, too, are the coral-limestones, which are formed in large measure of the hard corallia of certain actinozoa. On the nature and origin of limestones, v. H. C. Sorby's Presidential Address to the Geol. Soc., 1879 (*Quart. Journ. Geol. Soc.* 35, 56, 'Proc.'). also F. Sentt, 'Die Wanderungen u. Wandlungen d. Kohlens. Kalkes' (*Zeitsch. d. deutsch. Geolog. Ges.*, 13, 1861, 263).

When  $\text{CaCO}_3$  is deposited from thermal springs, the pp. usually takes the form of *aragonite*, the orthorhombic species of  $\text{CaCO}_3$ , harder and denser than calcite. The ppn. of aragonite is well illustrated by the *Sprudelstein* of Carlsbad. The water in which this is formed has a temperature of about  $73^{\circ}\text{C}$ ., and though containing only 0.29 p.c. of  $\text{CaCO}_3$ , it readily deposits this salt on cooling. The sprudelstein is commonly oolitic or pisolitic, each little sphere being formed of a series of concentric layers deposited successively around a nucleus, and thus imitating the oolitic structure familiar to geologists in various limestones. The experiments of G. Rose tended to show that when a solution of carbonate of calcium is warm or concentrated it deposits aragonite, while if cold or very dilute it throws down calcite. It has been shown by Credner that the deposition of aragonite is favoured by the presence of gypsum, strontianite, and certain other foreign bodies in the solution from which ppn. proceeds.

Calcareous matter deposited on a large scale is usually more or less impure, and hence limestones become argillaceous, bituminous, &c. On the solution of a limestone by natural solvents,

a variable amount of insoluble matter is left, and where the action has extended over long periods the residual impurities, by their accumulation, may acquire considerable importance: such, for instance, is the origin of the deposits on the chalk in this country known as 'clay-with-flints'; and the reddish earth so common in limestone caverns and known as 'cave-earth.'

• On the solution of limestones in nature, v. T. Mellard Reade, *Chemical Denudation in relation to Geological Time* [London, 1879].

*Origin of Dolomite.*—The origin of magnesium limestone, or *dolomite*, has long been a chemical enigma. Since dolomite frequently occurs in association with rock-salt, it has been suggested that it must be of lacustrine origin. Bischof, however, showed long ago the difficulty of simultaneously ppg.  $\text{CaCO}_3$  and  $\text{MgCO}_3$  from a solution containing these salts. At the beginning of the evaporation  $\text{CaCO}_3$  alone falls; towards the close of the process  $\text{MgCO}_3$  alone; and it is only at intermediate stages that the mixed carbonates are thrown down. It might, therefore, be expected that the geologist would find pure limestone below, succeeded by a deposit of dolomite, and followed above by pure magnesite—a sequence, however, which is not observed in nature. Indeed, dolomite seems to have been formed not so much by direct ppn. on the evaporation of waters in which the two carbonates co-existed as by certain chemical reactions.

Sterry Hunt has pointed out that the interaction between carbonate of sodium and the chlorides of magnesium and calcium in sea-water would give rise to dolomite, with simultaneous production of chloride of sodium, thus explaining the common association of dolomite with rock-salt. There seems no difficulty in providing the necessary quantity of  $\text{Na}_2\text{CO}_3$ , inasmuch as various soda-bearing silicates, notably the sodafelspars, are commonly suffering decomposition in nature by the action of carbonated waters, with consequent formation of  $\text{Na}_2\text{CO}_3$  and separation of silica. Another reaction suggested by Sterry Hunt is that which may occur between  $\text{CaCO}_3$  and  $\text{MgSO}_4$ ; the resulting  $\text{MgCO}_3$  may, under certain conditions, become associated with fresh  $\text{CaCO}_3$ , so as to form dolomite, which will then be accompanied by a precipitate of  $\text{CaSO}_4$ . As a matter of fact, nothing is more common than to find dolomite naturally associated with gypsum (*Chem. and Geol. Essays*, 1875, 90).

Hoppe-Seyler obtained dolomite by heating carbonate of calcium in a solution of bicarbonate of magnesium in a sealed tube at  $100^\circ\text{C}$ . (*Zeits. deutsch. geol. Ges.* 27, 509). Possibly in some cases dolomite has been formed under abnormal conditions of temperature. The crystalline dolomites, enormously developed in the triassic series of the Eastern Alps, are believed to be metamorphic rocks, or ordinary limestones which have become dolomitised (*v. infra*).

*Weathering of Rocks.*—Most rocks on or near the surface of the earth have suffered more or less chemical change by the natural action of air and water. This weathering usually takes the form of *oxidation* and *hydration*; thus, rocks such as basalt, which contain minerals rich in iron, exhibit along their joint-planes a rusty appearance, due to the formation of ferric hydrate. Deposits of brown iron-ore of great magnitude

may result from the alteration of masses of iron-pyrites. Such, too, is the origin of the *gossan*, or impure brown iron-ore commonly found in the upper part of mineral veins where anogenic action has been rife, and known to Continental miners as the *Chapeau de fer* or *Fiserne Hut*. Many clays and other rocks present in their unaltered condition a bluish or grey colour, due to the presence of finely-disseminated iron-pyrites, which in like manner decomposes on exposure, yielding ferrous sulphate, and finally ferric hydrate, and the rock thus assuming brown and yellow tints. (On the colour of certain oolitic rocks v. A. H. Church, *C. J.* [2] 2, 379.)

On the other hand, a process of *deoxidation* may frequently be traced in the natural alteration of rocks and minerals, the principal reducing agent being organic matter. Sulphates may thus be reduced to sulphides; whence in many cases the origin of iron-pyrites—a mineral commonly found in association with coal, fossil wood, shells and other organic remains (*v. Pepps, Trans. Geol. Soc.* 1, 399). In like manner gypsum may be reduced to the condition of sulphide of calcium; and this, if dissolved in water containing carbonic acid, will yield carbonate of calcium and sulphuretted hydrogen, the latter readily depositing free sulphur on exposure to the air. Hence probably the origin of the associated deposits of gypsum, sulphur, and limestone, so familiar to the geologist in Sicily and other sulphur-bearing localities. The removal of crystals of selenite from clays and other rocks may be due to similar reactions and not to mere solution (Duncan, *Q. J. Geol. Soc.* 22, 12).

It has long been known that the organic acids resulting from the decomposition of vegetable matter may exert a bleaching action upon red and brown rocks, by reducing the ferric oxide to a lower state of oxidation. It has been suggested that some of the finest white glass-making sands may have been derived from sands originally yellow or brown, but decolourised in this way. At the same time such reducing action appears incompetent to explain the local decolouration observed in many variegated rocks (*v. an important paper by G. Maw in Q. J. Geol. Soc.* 24, 351).

Hydration, though usually accompanying oxidation, may occur in nature without any other chemical change. A common illustration of such action is seen in the conversion of anhydrite into gypsum, by absorption of two molecules of water. This change is accompanied by a marked increase in bulk, 1 vol. of  $\text{CaSO}_4$  becoming 1.6 vol. of  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ . The galleries of deserted mines in which anhydrite has been worked have become closed by the swelling of the walls, consequent on hydration of the mineral. Geologists believe that a similar increment of bulk, occurring on a large scale in deep-seated deposits, may account for certain minor movements of the Earth's crust.

*Origin of Kaolin.*—It is commonly said that one of the most striking examples of weathering is afforded by the decomposition of the felspar in granitic and other rocks. Meteoric waters, containing carbonic and organic acids, readily attack feldspathic minerals, removing the alkalis in a soluble form, while the silicate of aluminium,

in a hydrated condition, remains behind as clay. *Kaolin*, or china-clay, the purest form of argillaceous matter, may thus be derived from felspar-bearing rocks, especially granites. It was seriously held that the great heat experienced in working the Comstock lode was due to the kaolinisation of the felspars in the surrounding rocks—a suggestion, however, entirely disproved by experiment. In Cornwall it is not uncommon to find granite in which the orthoclase, or potash-felspar, is more or less decomposed, while the associated silicates remain almost unaltered: such a rock is known as *china-stone* or *petunssite*; while a rock in which the felspar is entirely kaolinised is termed *china-clay rock* or *carclazite*. It is frequently held that the simple action of meteoric waters, charged with carbonic and organic acids, is sufficient to explain the origin of kaolin; but though kaolinisation may undoubtedly result from mere weathering, it seems that superficial action is incompetent to explain all the observed phenomena. The change appears rather to have been effected by means of solutions derived from deep-seated sources, circulating in the joints of the granite. It has often been pointed out that the decomposed granite is associated with minerals containing fluorine (like lepidolite) or fluorine and boron (like schorl). Von Buch in 1824, and Daubrée in 1841, suggested that the change has been due to hydrofluoric acid or other fluorides, which, acting upon the granite at an elevated temperature, would decompose the felspar, removing its alkali as a fluoride. Cassiterite ( $\text{SnO}_2$ ) is a common associate of the kaolinised granite, and there is reason to believe that this mineral has been produced by the agency of fluorine. Daubrée succeeded in producing crystals of  $\text{SnO}_2$  by passing the vapour of stannic chloride with steam through a heated porcelain-tube, the chloride having been used in place of the fluoride merely for convenience (v. Daubrée's *Études synthétiques de Géologie expérimentale*, Paris, 1879, where his researches are presented in a collected form. For Cornish kaolin v. J. H. Collins, *The Hensbarrow Granite*, Truro, 1878; and *Mineralog. Mag.* 7, 205).

**Metamorphism.**—A rock, whether of aqueous or of igneous origin, is said to be *metamorphic* when it has been altered not by atmospheric agencies but by some profounder influence which has so affected its structure and composition that its original character is no longer to be recognised by direct observation. Thus the intrusion of an igneous rock among sedimentary strata may give rise to changes known as *contact metamorphism*. By such action an ordinary limestone may be converted into a crystalline marble—a phase of metamorphism conveniently distinguished by A. Geikie as *marmorosis*. The production of a saccharoidal marble from an amorphous limestone under the influence of heat and pressure was illustrated by James Hall's experiments in the early part of this century.

The effects of contact metamorphism are partly physical and partly chemical. To the former class may be referred not only the crystallisation of limestone but the induration and even fusion of various other rocks, and the development of prismatic structure in the neigh-

bourhood of the heated mass. Among ordinary chemical effects may be noted the expulsion of water, the reddening of a calcined rock and the conversion of coal into a natural coke. But the most interesting phenomena are those attending the development of new minerals. Thus, a slate in the neighbourhood of an intrusive granite frequently contains garnets, chistolite, and other crystallised silicates; while metamorphic limestones may inclose rock-crystal, garnets, idocrase, micas, and other minerals which appear to have been produced by the rearrangement and crystallisation of the materials of the sand, clay, and other impurities originally present in the limestone. The ejected limestone blocks of Monte Somma, consisting originally of the Subapennine limestone, are rich in minerals of this character, and have lately been specially studied by J. H. Johnston-Lavis, of Naples, and by B. Mierisch (*Min. u. Pet. Mitt.* [N. F.] 8, 113 [1887]).

When metamorphic rocks extend over a wide area and are not visibly associated with igneous rocks to which their alteration may be referred, they are said to be due to *regional metamorphism*. The agencies by which such phenomena have been produced are exceedingly obscure, but while many of the changes are of a chemical and molecular character, it is evident that molar forces have been operating on a large scale. Of late years it has been recognised that the mechanical movements of the rocks have largely contributed to the production of the characteristic structures in those metamorphic rocks known as the crystalline schists, not only producing deformation of the constituent minerals, but indirectly causing the passage of one mineral into another. (On dynamic metamorphism v. J. Lehmann, *Entstehung d. altkrystallinischen Schiefer-Gesteine*, Bonn, 1884; Teall's *Brit. Petrog.*, 1888, cap. xiv.; *Études sur les schistes cristallins*, Int. Geol. Congress, 1888; A. Harker, *B. A.* 1885, 845. For contact-metamorphism, v. Delesse's *Études sur le métamorphisme des Roches*. For the subject generally consult Bonney's address to Geol. Soc., *Quart. Journ. Geol. Soc.*, 42, 55; and A. Irving, *Rock-metamorphism*, 1888.)

**Hydrothermal action.**—The effects of thermal metamorphic agencies, even in the neighbourhood of an igneous rock, are usually due, not so much to dry heat as to hydrothermal action. Although pure water at ordinary temperature and pressure is capable of slowly dissolving the common mineral-constituents of rocks (Rogers, *Am. S.* [2] 6, 401), its solvent action is vastly increased by the great heat and pressure to which it must be subjected in the deeper-seated portions of the earth's crust, where metamorphism, probably has its normal seat. Such action is well illustrated by the remarkable experiments of Daubrée. This observer found that when water was heated in strong glass tubes inclosed in thick wrought-iron cylinders, and exposed uninterruptedly to a temperature of at least 400°C. for several weeks, the glass was transformed into a hydrated silicate, analogous to a natural zeolite, while the interior of the tube became lined with a crust of small transparent crystals of quartz (*Géolog. expériment.* 168). In some cases the artificial crystals of

quartz lined the walls of the tube like the quartz in a natural geode (ib. 166).

The solvent action of water at great depths accounts for the peculiar composition of the water of geysers. Under enormous pressure and at a high temperature these waters are capable of decomposing the volcanic rocks which they traverse and of dissolving out silica. Thus, water from the Opal Spring in the Yellowstone National Park contained as much as 53.76 g. of silica to the imperial gallon (Leffmann). On the evaporation of such water the silica is deposited in a hydrated form as a kind of opal or siliceous sinter, known as *florite* or *geyserite* (v. A. C. Peale, 'Thermo-hydrology,' in *Twelfth Rep. U.S. Geol. and Geog. Survey of the Territories*, 2).

**Dolomitisation.**—Among cases of metamorphism, that of the alteration of a normal limestone into dolomite has long been recognised and variously explained. Von Buch and certain other German geologists, looking at the association of crystalline dolomite with basic igneous rocks in the Tyrol, held that these erupted masses had emitted vapours containing compounds of magnesium which had acted upon the neighbouring limestone, causing dolomitisation. In support of such a view it was pointed out by Durocher (*C. R.* 23, 64) that when fragments of limestone are heated with  $MgCl_2$  in a closed vessel, the limestone is partially converted into dolomite. Such an action, however, if it occurs at all in nature, must be limited to the immediate neighbourhood of the heated body evolving the magnesian vapours. In order to explain the alteration of large masses of limestone it is simpler to invoke the agency of percolating water holding compounds of magnesium in solution. Even where limestone has been dolomitised in contact with basalt, Bischof contended that the change was due to the action of water containing  $MgCO_3$ , resulting from the decomposition of the magnesian silicates in the igneous rock.

When water containing carbonate of magnesium percolates through a limestone, the magnesian salt tends to unite with part of the calcium carbonate so as to form a double salt, while  $CaCO_3$  is at the same time dissolved out. For every molecule of  $CaCO_3$  removed, a molecule of  $MgCO_3$  is introduced, the change being accompanied by a diminution of volume to the extent of 12 or 13 p.c. Now it is a remarkable fact that natural dolomites are frequently marked by a cellular or cavernous texture, and Élie de Beaumont long ago suggested that the cavities were due to shrinkage consequent on dolomitisation. It is estimated that in many magnesian limestones the hollows represent about 12 p.c. of the bulk of the rock. The sulphate and chloride of magnesium in sea-water may also transform limestone into dolomite, but according to Favre the action requires a temperature of  $200^\circ C$ , favoured by great pressure. (For a good review of the whole subject of dolomitisation v. A. H. Green's *Geology*, 3rd ed. 1882, 403; also Doelter & Hoernes, 'Chem.-Genet. Betracht. d. Dolomit,' in *Jahr. d. k.-k. Geol. Reichs.* 1875, 25, p. 298; with a full bibliography to date.)

$MgCO_3$  is not the only carbonate which has been introduced into certain limestones by second-

dary processes. In some cases beds of limestone have been more or less completely transformed into  $FeCO_3$ ,—a change well illustrated on a large scale in the important deposits of Cleveland ironstone in the Middle Lias of N.E. Yorkshire. Sorby believes that this ore has been formed from an oolitic limestone by percolation of water containing bicarbonate of iron in solution. Most of the fossil shells associated with the ore have suffered a like conversion, and in some cases the ferrous carbonate has been further changed into ferrio hydrate (*Proc. Geol. and Polyt. Soc. W. Riding*, 1856-7).

**Serpentinisation.**—The origin of serpentine has been a subject of much discussion, in which the geologist has had to appeal to the chemist. By most modern petrographers it is regarded as an altered eruptive rock, having been derived mainly from olivine. Pseudomorphs of serpentine after olivine are familiar to the mineralogist and an action similar to that which produced this alteration appears to have been concerned in the metamorphism of large rock-masses. This view has gained much credence of late years by the study of the microscopic structure of serpentine by Sandberger, Tschermak, Bonney, and other petrographers. Hydration is effected by water gaining access to the olivine through the irregular fissures by which the mineral is usually traversed; and in the case of ferriferous olivines the iron is deposited in the form of magnetite and limonite (v. Teall, *Brit. Petrog.*, 1888, p. 104).

While many serpentines suggest by their occurrence as dykes and bosses that they have been derived from eruptive rocks, others occur in beds intercalated among crystalline schists, especially in association with limestone. It has been supposed that such serpentine may have resulted from the alteration of dolomite or some other magnesian rock of aqueous origin. Sterry Hunt, who is specially familiar with the serpentines of the Laurentian series of Canada, has always argued against the derivation of serpentine from igneous rocks, and regards it simply as a product of direct precipitation from natural waters. He holds that by the decomposition of the various crystalline silicates in nature, soluble silicates of the alkalis and of lime are set free, and passing into streams are ultimately mixed with waters rich in magnesium salts—such as the sulphate or chloride in sea-water—when double decomposition ensues, and silicate of magnesium is precipitated in a gelatinous condition (*Trans. R. Soc. Canada*, 1, 165; *Mineral Physiology*, Boston, 1896, p. 427).

**Recent formation of minerals.**—Observations on the production of minerals under known conditions in historic times are of much interest to the geological chemist, inasmuch as they suggest the processes which may have operated in nature during geological time. Daubrée long ago called attention to the production of a series of minerals since the Roman period at the hot springs of Plombières in the Vosges. Around these springs the Romans had built walls of concrete, consisting of brick and stone cemented by mortar. By the action of the waters at  $50^\circ C$ . upon the concrete, there has been formed a series of minerals including chabasite, harmatome, mesotype, and other zeolites, associated

with opal, caliche, &c. Similar effects have been observed at other Roman baths, as at Luxeuil (Haute Saône) and at Bourbonne-les-Bains (Haute Marne) (v. *Géologie Expérimentale*, p. 179; and Percy's *Lectures on Chemical Geology* in C. N. 9, 100).

*Geodes*.—The production of certain minerals at the Roman stations just cited recalls the natural formation of similar substances in the cavities of basaltic and other rocks. These cavities, though perhaps in some cases due to the removal of pre-existing crystals by solution, usually represent bubbles produced by the disengagement of gas or steam at a time when the igneous rock was in a plastic condition. The minerals occurring in such cavities are of secondary origin, having been introduced through the medium of solutions permeating the rock long after solidification. When the vesicles are filled with mineral matter the rock is said to be *amygdaloidal*; if the cavities are not completely filled, and the walls are lined with crystals, they are termed *geodes*. The most common of these secondary minerals are calcite and silica, the latter frequently forming agates. In an agate, regular layers of colloidal, crypto-crystalline, and crystalline, silica, succeed each other with regularity. The exact manner in which the silica has been introduced, and precipitated on the walls, has given rise to much discussion, but a clue is suggested by the experiments of Pankhurst and Anson on the artificial production of agates (*Mineral Mag.* v. 34).

*Origin of Mineral Veins*.—The deposition of secondary minerals in the cavities of rocks tends to throw light upon the formation of mineral veins, or lodes—a subject on which the geologist has frequently appealed to the chemist. It is now generally held that these veins represent fissures filled in by deposition of mineral matter from a state of solution. The chief difficulty is to trace the metalliferous minerals to their origin. The most promising modern researches are those of Prof. Fridolin Sandberger, of Würzburg (*Untersuchungen über Erzgänge*, i. 1882; ii. 1885). By comparative analyses of the ore, the veinstone, and the country rock, he has shown that the contents of the lode have been derived in certain cases from the neighbouring rocks, and that the ores have probably obtained their metallic elements from the common constituents of the crystalline rocks, which had not previously been suspected to contain such metals. Analyses of ordinary rock-forming minerals, like mica, augite, hornblende, and olivine, revealed the presence in them of a large number of the heavy metals. Nor is it only in the crystalline rocks that such metals occur, Dicaulafut having shown that many of them are widely distributed in minute proportion through the stratified rocks. Such an occurrence is readily explicable by the fact that most sedimentary strata have been derived, directly or indirectly, from the disintegration of the older crystalline rocks. Thus it has been shown by A. Dick that minerals containing zirconium and titanium are widely distributed through sands of tertiary age (*Nature*, 86, 91), and Teall has found similar minerals in various clays (*Min. Mag.* 7, 201).

Some interesting phenomena tending to illustrate the origin of certain mineral veins have been studied in districts in California and Nevada, where hydrothermal action is rife. Hot water, steam, carbonic acid, sulphuretted hydrogen, and other gases escape from fissures in volcanic rocks, and on the walls of these fissures they deposit siliceous sinter associated with free sulphur, cinnabar, iron-pyrites, and other metalliferous minerals, including metallic gold—the whole assemblage being suggestive of the contents of certain veins (v. A. J. Phillips, *P. M.* 1068, 321; Laur, *Ann. d. Mines*, 3, 423).

Durocher and some other observers have argued in favour of many metallic minerals in lodes having been produced by sublimation. In Durocher's experiments he succeeded in producing galena, iron-pyrites, zinc-blende, and other metallic sulphides by passing certain vapours through glass tubes at a high temperature (*C. R.* 33, 823; 42, 850).

As an illustration of the production of thin strings of metallic minerals by decomposition of vapours, attention may be called to the frequent occurrence of specular iron ore sublimed in the crevices of lava, this mineral having obviously been formed by the reaction of steam and ferric chloride:  $\text{Fe}_2\text{Cl}_6 + 3\text{H}_2\text{O} = \text{Fe}_2\text{O}_3 + 6\text{HCl}$ . (On the general subject of mineral veins, v. J. A. Phillips, *Ore Deposits*, London, 1884; Von Cotta, *Erzlagerstätten*, Freiberg, 1859 [Translation by F. Prime, New York, 1870]; and Von Groddeck, *Lagerstätten der Erze*, Leipzig, 1879.)

*Chemistry of the Volcano*.—The chemical operations involved in volcanic phenomena are extremely obscure. It is generally admitted that water is the prime factor in the production of these phenomena, and as the temperature prevailing at volcanic foci probably exceeds the critical point of water it must exist in the form of vapour, notwithstanding the enormous pressure to which it is subjected: possibly the temperature is so high that the water is dissociated. Fouqué found in the lava of Santorin of 1876 a notable quantity of free hydrogen co-existing with free oxygen. The volcanic vapours associated with steam are chiefly  $\text{HCl}$ ,  $\text{SO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{S}$ , free  $\text{O}$ ,  $\text{H}$ , and  $\text{N}$ , and sometimes  $\text{NH}_3$  and  $\text{CH}_4$ . The  $\text{HCl}$  may be due to access of sea-water, most volcanoes being situated on islands, or, if on the mainland, near to the sea-coast. Ricciardi has found that finely powdered granite and lava mixed with pure  $\text{NaCl}$  evolve  $\text{HCl}$  when heated, the quantity being increased by blowing in a current of steam (*Gazzetta*, 16, 38). The sublimed products of volcanic rocks include a large number of metallic chlorides, notably those of  $\text{NH}_3$ ,  $\text{Na}$ ,  $\text{Fe}$ ,  $\text{Cu}$ ,  $\text{Ca}$ , and  $\text{Mg}$ .

The  $\text{SO}_2$  of volcanic exhalations has been referred by Ricciardi to the reaction of silica with  $\text{CaSO}_4$  and  $\text{MgSO}_4$ , whereby silicates are produced, with separation of sulphur trioxide which is resolved into sulphur dioxide and oxygen. He found that granite mixed with the sulphates cited above would evolve  $\text{SO}_2$  when heated. By the interaction of  $\text{SO}_2$  and  $\text{H}_2\text{S}$  free sulphur is produced and deposited as an incrustation on the lava. By oxidation, sulphuric acid is developed, and this by its action on the volcanic rocks tends to decompose them,

with production of various sulphates. Thus it comes about that alum is manufactured in the crater of Vulcano, one of the Lipari Islands, and at the Solfatara, near Naples. The term 'solfatara' is now used by geologists as a general designation for a volcano which is approaching extinction and emits only vapours. Long after other emanations cease,  $\text{CO}_2$  may be exhaled, as in many localities in the Eifel and in Auvergne. Boric acid, in a finely-divided condition, is produced from the nearly exhausted crater of Vulcano, and from the *molette* of Tuscany where it has long been utilised industrially. (On the general subject of volcanoes, v. Judd's volume in the International Science Series.)

**Synthesis of Igneous Rocks.**—The artificial reproduction of many igneous rocks has been successfully accomplished in recent years by Fouqué and Lévy in the geological laboratory of the Collège de France, in Paris. (For a full description of these researches, v. their *Synthèse des Minéraux et des Roches*, Paris, 1882.) These observers have shown that a number of basic eruptive rocks can be formed by the fusion of their constituents, and that the products, examined in thin sections under the microscope, are identical in structure and composition with the corresponding natural rocks. It had previously been supposed that water, in some form, played a conspicuous part in the liquefaction of igneous rocks, and that this was in fact due not to dry fusion but rather to hydrothermal action. The syntheses performed by Fouqué and Lévy controverted this view, inasmuch as they were effected solely by dry igneous fusion, without the presence of water or any other volatile medium, and without flux or other chemical agent.

The raw materials employed by these experimentalists were either the component minerals of the rocks to be produced (such as feldspar, augite, &c.), or the chemical constituents of these minerals (silica, alumina, lime, &c.). These materials, corresponding in their relative proportions with the composition of the rock to be imitated, were introduced, in a pulverised condition, into a platinum crucible of about 20 c.c. capacity, furnished with a cover. The crucible was heated in a furnace of Porquignon and Leclerc's type, heated by a Schlösing blowpipe, whereby it could be rapidly raised to a white heat, or reduced at will to a lower temperature, and the heat maintained constant for a long period. The first fusion at a white heat always yielded an isotropic glass, and this if cooled suddenly maintained its vitreous character. But if the fused product was kept for some time at a temperature below a white heat, yet above that of the melting-point of the glass, various crystalline products were developed; and by subjecting the material to successively diminishing temperatures, other products crystallised out, the least fusible being the first to separate.

By a process of fractional crystallisation conducted in this way, Fouqué and Lévy imitated the conditions which appear to have obtained during the formation of volcanic rocks, where the crystallised constituents represent successive periods of consolidation. Artificial basalt was obtained by fusing a mixture of the

elements of olivine, augite, and labradorite, and subjecting the resulting black glass to a bright red heat for 48 hours, when the olivine, which is the least fusible component, was found to be crystallised. Then on submitting the mass to a cherry-red heat for another 48 hours, the microlitic crystals of the more fusible minerals separated: these were the lath-shaped crystals of plagioclase and augite, which may be regarded as minerals of the second period of consolidation. Some of the most remarkable experiments were those on the so-called ophites. These are doleritic rocks, in which the augite forms comparatively large plates moulded around the crystals of plagioclase; the former having evidently been of subsequent consolidation to the latter. By a succession of suitable coolings and re-heatings this ophitic structure was perfectly imitated.

Notwithstanding the remarkable success with which the basic igneous rocks have lately been imitated, all experiments on the synthetic formation of the acid rocks have hitherto been fruitless. The reproduction of these natural products forms one of the most interesting fields of investigation left open to the geological chemist. F. W. R.

**GEORETIC ACID**  $\text{C}_{12}\text{H}_{22}\text{O}_4$ . A waxy acid obtained from lignite found near Weissenfels. Extracted by 80 p.c. alcohol, and ppd. by  $\text{Pb}(\text{OAc})_2$ ; the acid is liberated from the pp. by  $\text{HOAc}$  (Brückner, *J. pr.* 57, 1). Small needles (from alcohol). Its solution gives a dirty-green pp. with cupric acetate. From similar lignite Brückner isolated resinous leucopetrin  $\text{C}_{20}\text{H}_{34}\text{O}_2$ , crystallising from alcohol in tufts of needles [above  $100^\circ$ ]; geomyrin  $\text{C}_{18}\text{H}_{30}\text{O}$ , [c.  $82^\circ$ ] crystallising from alcohol in minute hair-like needles; geocerlic acid  $\text{C}_{20}\text{H}_{34}\text{O}_2$ , [ $82^\circ$ ]; and geocerin  $\text{C}_{20}\text{H}_{34}\text{O}$ , [ $80^\circ$ ]. Geocerin is a neutral wax.

**GERANIENE**  $\text{C}_{15}\text{H}_{26}$ , ( $163^\circ$ ). S.G.  $\frac{22}{4}$  843. A terpene obtained by treating oil of geranium with  $\text{P}_2\text{O}_5$  (O. Jacobsen, *A.* 157, 239). By treatment with half the calculated quantity of iodine it is converted into cymene (Oppenheim a. Pfaff, *B.* 7, 625). Gives a liquid hydrochloride.

**GERANIOL**  $\text{C}_{15}\text{H}_{26}\text{O}$ , (233°). S.G.  $\frac{14}{8}$  885. A compound occurring in oil of geranium (O. Jacobsen, *A.* 157, 232; Gintl, *Ph.* [3] 10, 24). Oil. Inactive to light. Fragrant smell like roses. Miscible with alcohol and ether. With calcium chloride at  $50^\circ$  it forms a crystalline compound  $(\text{C}_{15}\text{H}_{26}\text{O})_2\text{CaCl}_2$ , decomposed by water. Slowly oxidised by air. Potash fusion forms isovaleric acid. Neutral aqueous  $\text{KMnO}_4$  forms acetic and isovaleric acids. Even boiling baryta-water slowly forms isovaleric acid. Chromic acid mixture forms also succinic acid.  $\text{HNO}_3$  forms nitrobenzene,  $\text{HCy}$ , oxalic acid, and a resin, but no camphoric acid.

Geranyl chloride  $\text{C}_{15}\text{H}_{21}\text{Cl}$ . S.G.  $\frac{22}{10}$  1020. From geraniol and gaseous  $\text{HCl}$ . Inactive oil smelling like camphor. Alcoholic  $\text{AgNO}_3$  ppt., even in the cold all the  $\text{Cl}$  as  $\text{AgCl}$ .  $\text{KCy}$ ,  $\text{KCyS}$ ,  $\text{KNO}_3$ , and other  $\text{K}$  salts displace the  $\text{Cl}$  by their acid residues.

Geranyl bromide  $\text{C}_{15}\text{H}_{21}\text{Br}$ . Oil.

Geranyl iodide  $\text{C}_{15}\text{H}_{21}\text{I}$ . Oil. From the chloride and cold alcoholic  $\text{KI}$ .

**Di-geranyl 'oxide** ( $C_{16}H_{32}O$ , (187°-190°). From geranyl chloride and potassium geraniol  $C_{16}H_{32}OK$ . Oil, smelling of peppermint.

**Di-geranyl sulphide** ( $C_{16}H_{32}S$ ). From  $C_{16}H_{32}Cl$  and alcoholic  $K_2S$ . Heavy yellowish oil. With  $HgCl_2$  it gives a compound insol. alcohol. When heated it gives geraniene.

**GERMANIUM.** Ge. At. w. 72.3. Mol. w. unknown, as V.D. has not been determined. [c. 900°] (Winkler, *J. pr.* [2] 34, 177). S.G.  $\frac{100}{20}$  5.469 (W., l.c.). S.H. 100°-440° -0737 to -0757 (W., l.c.). Sharpest lines in emission-spectrum 6020, 5892, 4684.5 (Kobb, *W. A.* 29, 670). L. de Boisbaudran says that the characteristic lines are 4680 and 4226 (*C. R.* 102, 1291).

In 1885 a silver ore from the Himmelsfürst mine, near Freiberg, was recognised by Richter as a new mineral species; to it he gave the name of *argyrodite*. The mineral was carefully analysed by Winkler with the result that the percentages of Ag, S, Hg, Fe, and Zn found added up to 93.94. After much labour, Winkler was able to announce that the rest of the mineral was composed of a new element, to which he gave the name *germanium* (*B.* 19, 210). Winkler was inclined to regard germanium as belonging to the Sb-Bi family, but fuller investigation showed it to be identical with *ekasilicon*, the properties of which had been foretold by Mendelejeff, and the position of which had been indicated by him as group IV., series 5. The reasoning which led Mendelejeff to his statement of the properties of *ekasilicon* was similar to that on which he based his prediction of the properties of *eka-aluminium*, with which element gallium was found to be identical (*v. GALLIUM, Chemical relations of*, p. 598).

**Occurrence.**—Ge forms about 6.9 p.c. of *argyrodite*. The composition of this mineral is approximately expressed by the formula  $2Ag_2S.GeS_2$ ; it contains about .66 p.c. Fe, .22 p.c. Zn, and .31 p.c. Hg. Ge has also been found in *euzenite* to the extent of about 7 p.c. (Krüss, *B.* 21, 131).

**Preparation.**—Powdered *argyrodite* is heated to moderate redness with calcined  $Na_2CO_3$  and flowers of S; the product is extracted with water, and exactly enough  $H_2SO_4$  is added to decompose the  $Na_2S$ . After standing for a day the liquid is filtered, and  $HClAq$  is added so long as a pp. forms. The liquid is saturated with  $H_2S$ , and filtered; the pp. is washed with 90 p.c. alcohol saturated with  $H_2S$ . The sulphide of Ge thus obtained is roasted at a low temperature and warmed with  $HNO_3Aq$ . The oxide thus produced is strongly heated, and then reduced, either by heating in  $H_2$  or by making into small balls with starch and water, and heating to bright redness between layers of charcoal, and then melting under borax (Winkler, *J. pr.* [2] 34, 177). For another method *v. Winkler, J. pr.* [2] 36, 177.

**Properties.**—Greyish-white, lustrous, very brittle; melts at c. 900°, and crystallises, in regular octahedra on cooling. Only slightly volatilised by heating in  $H$  or  $N$  at 1850° (V. Meyer, *B.* 20, 497). Unchanged in air at ordinary temperature, but oxidised when heated in state of powder. Dissolved by  $H_2SO_4Aq$  but

not by  $HClAq$ . The atom of Ge is tetravalent in the gaseous molecules  $GeCl_4$  and  $GeI_4$ .

The at. w. has been determined by analysing  $GeCl_4$ , and determining the V.D., and hence mol. w. of the same compound, and also  $GeI_4$  and  $GeS$  (Winkler, *J. pr.* [2] 34, 177). The value 72.3 is confirmed by measurements of the S.H. of Ge at 100°-400°. Lecocq de Boisbaudran has also calculated the at. w. from observations of the spectral lines of Ge (*C. R.* 102, 1291). The difference between the mean wave-lengths of the characteristic lines of Ge and Si is 443, and between Ge and Sn the difference is 624; this may be stated as 443 ( $1 + .4051$ ) = 624. In the cases of Ga and Al the difference is 149, and the difference between Ga and In is 205; this may be stated as 149 ( $1 + .38584$ ) = 205. The difference between the at. ws. of Ga and Al is 42.4, and the difference for Ga-In is 43.6; this may be stated as 42.4 ( $1 + .028302$ ) = 43.6. The difference between the at. ws. of Si and Sn is 90. From these data the number 72.31 is found for the at. w. of Ge, assuming that the relation between variation of at. ws. and wave-lengths in the three elements Si, Ge, Sn is the same as in the three elements Al, Ga, In (*v. GALLIUM, Chemical Relations of*, p. 598).

Germanium belongs to the same family as Si, Sn, and Pb; these four elements form the odd-series members of Group IV. Ge is both metallic and non-metallic in its chemical relations. The oxide  $GeO_2$  dissolves in acids, but no salts have yet been isolated; this oxide also dissolves in  $KOH$  and  $K_2CO_3$  when fused with these salts, and probably forms germanates analogous to the stannates;  $GeS_2$  also dissolves in alkaline hydrosulphides probably forming thiogermanates. The existence of the two oxides and sulphides  $GeO$  and  $GeO_2$ ,  $GeS$  and  $GeS_2$ ; the composition and properties of  $GeCl_4$ ,  $GeI_4$ , and  $GeF_4$ ; the formation of liquid  $GeHCl_3$ , analogous to  $SiHCl_3$  and  $CHCl_3$ , and of liquid  $Ge(C_2H_5)_4$ , similar to  $Si(C_2H_5)_4$ ; and the isolation of  $H_2GeF_6$  and salts of this acid; these mark the similarity between Ge and Si. Ge also appears to be capable of replacing Si in ultramarine.

**Reactions.**—1. Powdered Ge heated in air burns to  $GeO_2$ .—2. Oxidised to  $GeO_2$  by nitric acid.—3. Dissolves in sulphuric acid, but not in hydrochloric acid.—4. Combines directly with chlorine, bromine, and iodine, to form  $GeX_4$ .—5. Heated in a current of hydrogen chloride  $GeHCl_3$  is formed.—6. Heated with mercuric chloride or bromide  $GeCl_4$  or  $GeBr_4$  is produced.

**Detection and Estimation.**—The most characteristic reaction of Ge compounds is the production of white  $GeS_2$  by saturating an alkaline solution with  $NH_4HS$ , and then adding excess of a mineral acid. In estimating Ge, excess of  $NH_4HS$  is added to an alkaline solution, a large excess of dilute  $H_2SO_4Aq$  is then added, and the liquid is saturated with  $H_2S$ ; after standing 12 hours the ppd.  $GeS_2$  is collected, and washed with dilute  $H_2SO_4Aq$  saturated with  $H_2S$ ; the pp. is then washed off the filter, the residue on the filter is dissolved in ammonia, and this solution, together with the water used in washing off the pp., is evaporated to dryness in a weighed porcelain crucible, the main portion of the pp.

is now placed in the crucible, and the whole is evaporated to remove adhering  $\text{H}_2\text{SO}_4$ ; the residue is heated, nitric acid is added, and the whole is again evaporated and heated strongly; the residue is now digested with ammonia (to remove  $\text{H}_2\text{SO}_4$ ), then dried, heated strongly, and weighed as  $\text{GeO}_2$ . If the Ge is obtained as a thio salt, along with thio salts of Sb, As, and Sn, the solution is diluted to a definite volume, a measured portion is boiled with excess of normal  $\text{H}_2\text{SO}_4$ , and the residual  $\text{H}_2\text{SO}_4$  is determined volumetrically; the quantity of  $\text{H}_2\text{SO}_4$  required to neutralise the solution is thus determined; the proper quantity of  $\text{H}_2\text{SO}_4$  is then added to another measured portion of the liquid, and, after standing 12 hours, the liquid is filtered and evaporated to a small volume;  $\text{NH}_4\text{Aq}$  and  $\text{NH}_4\text{HS}$  are added, then excess of  $\text{H}_2\text{SO}_4$ , and the Ge is pptd. as  $\text{GeS}_2$  by saturating with  $\text{H}_2\text{S}$  (*v. supra*).

**Germanium bromide  $\text{GeBr}_4$ .** A strongly fuming colourless liquid, which solidifies a little below  $0^\circ$  to white crystals; decomposed by water with ppn. of  $\text{GeO}_2$  and production of much heat. Formed by heating Ge in Br, or with  $\text{HgBr}_2$  (Winkler, *J. pr.* [2] 36, 177).

**Germanium chloride  $\text{GeCl}_4$ .** Mol. w. 213.78. (86°). V.D. 107.5 at  $200^\circ$  to c.  $650^\circ$  (Nilson a. Pettersson, *Z. P. C.* 1, 27). S.G.  $\frac{190}{15}$  1.887. Critical temp. =  $276.9^\circ$  (N. a. P.) (vapour-pressures, *v. N. a. P., l.c.*). A thin colourless liquid, fuming in air; decomposed by water to  $\text{GeO}_2$ ; partially reduced to Ge by heating in H. Formed by heating Ge in Cl, shaking the product with Hg and distilling; or by heating powdered Ge with 8 times its weight of  $\text{HgCl}_2$  (W., *J. pr.* [2] 34, 177).

When HCl is passed over heated  $\text{GeS}_2$ , a chloride lower than  $\text{GeCl}_4$  is probably obtained.

**Germanium chloroform  $\text{GeHCl}_3$ .** Mol. w. 179.41. V.D. at  $178^\circ$  80.3. A thin colourless liquid, boiling at  $72^\circ$ : formed by gently heating Ge in dry HCl, and separating the heavier liquid from the lighter (separation of the distillate into two layers takes place slowly) (W., *J. pr.* [2] 36, 177).

**Germanium ethide  $\text{Ge}(\text{C}_2\text{H}_5)_4$ .** Mol. w. 188.06. V.D. 128. A colourless liquid of slightly alliacious odour; boiling at  $160^\circ$ . Prepared by mixing  $\text{ZnEt}_2$  with  $\text{GeCl}_4$ , and keeping the mixture cold, as the reaction occurs violently. Slightly lighter than, and immiscible with, water. Unchanged by mixture with oxygen at ordinary temperatures. Burns in air to  $\text{GeO}_2$  (W., *l.c.*).

**Germanium fluorhydric acid  $\text{H}_2\text{GeF}_6\text{Aq}$ .** When vapour of  $\text{GeF}_4$  (obtained by strongly heating  $\text{GeF}_3\cdot 3\text{H}_2\text{O}$ ) is led into water, the solution contains the acid  $\text{H}_2\text{GeF}_6$  (W., *l.c.*).

**POTASSIUM GERMANIO-FLUORIDE  $\text{K}_2\text{GeF}_6$ .** (W., *l.c.*; also Krüss a. Nilson, *B.* 20, 1696). Obtained by adding  $\text{KHF}_4$  to a solution of  $\text{GeO}_2$  in  $\text{HFAq}$  (N. a. P.), or by using KCl instead of  $\text{KHF}_4$  (W.), allowing the pp. to settle, filtering, and drying at dull red heat. According to N. a. P. the salt is melted without loss of weight at bright redness; and according to W. the salt loses weight above a red heat. Not hygroscopic. S. at  $100^\circ$  = 2.6 (N. a. P.). Crystallises in hexagonal forms;  $\alpha:\beta$  = 1:80389; isomorphous with  $(\text{NH}_4)_2\text{SiF}_6$  (N. a. P.).

**Germanium fluoride  $\text{GeF}_4\cdot 3\text{H}_2\text{O}$ .** Very deliquescent crystals, obtained by dissolving  $\text{GeO}_2$  in conc.  $\text{HFAq}$ , and evaporating over  $\text{H}_2\text{SO}_4$ . When heated,  $\text{HF}$  and  $\text{H}_2\text{O}$  are evolved, and some  $\text{GeO}_2$  is formed; heated to redness  $\text{GeF}_4$  is evolved, and about half the Ge remains as  $\text{GeO}_2$ . Pure  $\text{GeF}_4$  has not yet been obtained; Winkler (*J. pr.* [2] 36, 177) tried to prepare it, (1) by the action of H on heated  $\text{K}_2\text{GeF}_6$ ; (2) by heating  $\text{GeF}_3\cdot 3\text{H}_2\text{O}$  in dry  $\text{CO}_2$ ; (3) by heating together  $\text{GeO}_2$ ,  $\text{CaF}_2$ , and  $\text{H}_2\text{SO}_4$ ; (4) heating a mixture of  $\text{K}_2\text{GeF}_6$  with  $\text{H}_2\text{SO}_4$ .  $\text{GeF}_4$  is doubtless a solid capable of being volatilised (W.).

**Germanium iodide  $\text{GeI}_4$ .** Mol. w. 578.42. [ $144^\circ$ ]. ( $350^\circ$ – $400^\circ$ ) (W., *J. pr.* [2] 34, 177). V.D. at  $440^\circ$  272.5 (Nilson a. Pettersson, *Z. P. C.* 1, 36). Dissociation, probably into  $\text{GeI}_2$  and I, begins c.  $650^\circ$ . A yellow, very hygroscopic solid, vapour is inflammable; mixed with air and ignited, detonates feebly. Produced by heating Ge in a current of  $\text{CO}_2$  containing I vapour.

**Germanium oxides.**  $\text{GeO}$  has probably been isolated.  $\text{GeO}_2$  is a well-marked body.

**GERMANIC OXIDE  $\text{GeO}_2$ .** Produced by burning Ge in O; or by oxidising Ge by  $\text{HNO}_3$ ; or preferably by decomposing  $\text{GeCl}_4$  by water. Dense white gritty solid; S.G.  $\frac{190}{15}$  4.703. S. at  $20^\circ$  = 4; at  $100^\circ$  = 1.05 (W., *J. pr.* [2] 34, 177). Separates from solution in water as microscopic rhombic crystals. Aqueous solution has a sour taste.  $\text{GeO}_2$  dissolves readily in fused  $\text{KOH}$  and  $\text{K}_2\text{CO}_3$ . Probably forms salts with acids, but none has yet been isolated.

**GERMANIOUS OXIDE  $\text{GeO}$ .** Described by Winkler as obtained by boiling  $\text{GeCl}_4$  with  $\text{KOH Aq}$ , and heating the hydroxide (probably  $\text{GeO}_2\cdot\text{H}_2\text{O}$ ) thus formed in  $\text{CO}_2$ ; but there are doubts as to the isolation of  $\text{GeCl}_4$ , inasmuch as the substance formerly supposed to be this chloride has been shown to be  $\text{GeHCl}_3$  (W., *J. pr.* [2] 36, 177).  $\text{GeO}$  is also formed in small quantity when powdered Ge is melted under borax.  $\text{GeO}$  is described as a greyish-black solid; e. sol.  $\text{HCl Aq}$ , forming a solution which reduces  $\text{KMnO}_4\text{Aq}$  to  $\text{KMnO}_4\text{Aq}$  and ppts. Au and Hg from their salts.

**Germanium oxychloride (?)  $\text{GeOCl}_2$ .** When Ge is heated in dry HCl, two liquids of almost the same S.G. are obtained. The distillate slowly separates into two layers; the lighter is an oxychloride, probably  $\text{GeOCl}_2$ . Winkler (*J. pr.* [2] 36, 177) describes it as a colourless, oily, non-fuming liquid, which adheres to glass, and boils much above  $100^\circ$ , seemingly without decomposition.

**Germanium, salts of.**  $\text{GeO}$ , probably forms salts by dissolving in acids, but none has yet been isolated.

**Germanium sulphides.** Both  $\text{GeS}$  and  $\text{GeS}_2$  have been isolated.

**GERMANIC SULPHIDE  $\text{GeS}_2$ .** Obtained by adding  $\text{NH}_4\text{HS}$  to an alkaline solution of  $\text{GeO}_2$ , then adding considerable excess of  $\text{H}_2\text{SO}_4\text{Aq}$ , saturating with  $\text{H}_2\text{S}$ , washing first with  $\text{H}_2\text{SO}_4\text{Aq}$ , saturated with  $\text{H}_2\text{S}$  and then with alcohol, and drying *in vacuo*. A white powder. Heated in dry  $\text{CO}_2$ , it is partly volatilised, and apparently also partially decomposed. If  $\text{GeS}_2$  is washed with water until free from acid, and then suspended in water, an emulsion is formed which

requires several weeks to clear. About 1 part of the sulphide treated thus dissolves in 223.1 parts water; the solution is feebly acid to litmus; it soon decomposes with evolution of  $H_2S$ .  $GeS_2$  dissolves easily in alkaline hydrosulphides, probably with formation of thiogermanates.

**GERMANIOUS SULPHIDE**  $GeS_2$ . Mol. w. 104.28. V.D.  $1100^\circ-1500^\circ=48$  (Nilson a. Pettersson, Z. P. C. 1, 37). Greyish-black plates; very lustrous; red by transmitted light. Obtained by heating  $GeS_2$  in a slow current of  $H_2$ . Heated in air gives  $GeO_2$ . Dissolves easily in warm KOH aq. giving residue of  $Ge$ ; addition of  $H_2S$  to this solution ppt.  $GeS_2$  as a reddish-brown amorphous solid. M. M. P. M.

**GINGEROL**. An alkaline substance said to occur in ginger, the root of *Zingiber officinalis* (Thresh, Ph. [3] 12, 721). According to Thresh, the ethereal extract contains, besides gingerol, three resins  $C_{18}H_{34}O_2$ ,  $C_{26}H_{50}O_{10}$ , and  $C_{34}H_{66}O_{18}$ , and a terpene. By extracting ginger with alcohol, and distilling the extract with steam, Stenhouse and Groves (C. J. 31, 553; cf. Papoušek, A. 81, 352) obtained a light essential oil which yielded protocatechuic acid on fusion with soda.

**GINGKOLIC ACID**  $C_{21}H_{34}O_8$  [35?]. Occurs in the fruit of *Ginkgo biloba* (Schwarzenbach, J. 1857, 529; Viert. pr. Pharm. 6, 424).

**GLASS**. A mixture of K or Na silicate, or of ooth, with one or more silicates insol. water, such as silicate of Al, Ba, Ca, Fe, Pb, Mn, Mg, or Sr. Pure silicate of K or Na is acted on by water; silicate of Ca is decomposed by acids; but a mixture of the two is only very slowly acted on by water or the commoner acids. The greater the proportion of silica and alumina in the glass, the less fusible is it, and the more slowly is it acted on by acids.

Glass is slowly acted on by hot water; the more readily the greater the proportion of soda or potash in the glass. Glass is corroded or etched by HF aq. with formation of gaseous  $SiF_4$ . Glasses poor in silica are acted on by most acids, which dissolve out bases and separate silica. Potash or soda dissolves out silica from glass, especially when the solutions are hot and concentrated. Lead glass is blackened by heating owing to reduction of some of the Pb silicate to Pb. For details regarding different kinds of glass, v. DICTIONARY OF TECHNICAL CHEMISTRY. M. M. P. M.

**GLAUCINE**. An alkaloid obtained by Probst (A. 81, 241) from the leaves of the yellow horned poppy (*Glaucium flavum*) growing on sandy seashores. Colourless crystals of nacreous scales (from water). It is ppd. from solutions of its salts by  $NH_3$  as a curdy mass which after some time becomes pitchy. It is m. sol. hot water, v. sol. alcohol and ether. Tastes bitter. Its solution is alkaline in reaction. Hot  $H_2SO_4$  gives a violet colour; on adding water a red solution is formed, whence  $NH_3$  throws down an indigo-blue pp. The hydrochloride, sulphate, and phosphate of glaucine are crystalline, and v. sol. water and alcohol, insol. ether.

**GLAUCOMELANIC ACID** v. ELLAGIC ACID.

**GLAUCOPICRINE**. An alkaloid contained in the roots of *Glaucium flavum* (sive luteum) (Probst, A. 81, 254). Granular crystals, sol. water and alcohol, sl. sol. ether. Its salts have

an extremely bitter and nauseous taste. Animal charcoal removes glaucopicroine from solutions of its salts. Hot conc.  $H_2SO_4$  gives a dark green pitchy product, insol. water, acids, and ammonia. The hydrochloride crystallises in rhomboidal plates or in bundles of prisms, sol. water, insol. ether. The sulphate and phosphate are also crystallisable.

**GLIADIN** v. PROTEIDS.

**GLOBIN** v. HÆMOGLOBIN and PROTEIDS.

**GLOBULARIN**  $C_{18}H_{30}O_4$ . Occurs in the leaves of *Globularia Algyptum* (Walz, N. J. P. 13, 281; Heckel, A. Ch. [5] 28, 72; C. R. 95, 90). Amorphous; sol. water, alcohol, and ether. Tastes bitter. Acid in reaction. Ppd. from its aqueous solution by iodine and by tannin. Resolved by boiling dilute acids into glucose and globularin  $C_{18}H_{30}O_4$ . Globularin is converted into cinnamic acid by boiling KOH aq.

**GLOBULIN** v. PROTEIDS.

**GLOBULOSE** v. PROTEIDS.

**GLUCIC ACID**  $C_6H_{12}O_6$  aq. (R.);  $C_6H_{12}O_6$  (M.). Glycic acid.

**Formation**.—1. A solution of glucose is saturated with lime or baryta and left for several weeks. On adding lead subacetate a bulky pp. of lead glucoate is formed (Peligot, A. Ch. 67, 154).—2. Glucose melted at  $100^\circ$  in its water of crystallisation is mixed with warm conc. KOH aq.; as soon as the first reaction has ceased the liquid is diluted and the glucic acid ppd. by lead subacetate (Perroz).—3. Cane-sugar is boiled with dilute  $H_2SO_4$  in contact with the air. The product is filtered, neutralised by  $CaCO_3$ , evaporated to dryness, dissolved in a little water, and mixed with alcohol which ppt. calcium apoglucoate while acid calcium glucoate remains in solution (Mulder, A. 36, 243).

**Properties**.—Amorphous mass, v. sol. water and alcohol. Turns brown at  $100^\circ$ . The aqueous solution turns brown when boiled in contact with the air or with dilute  $H_2SO_4$  or HCl aq., apoglucoic acid being among the products. According to Grote and Tollens (A. 175, 181) the calcium glucoate of Mulder is calcium levulic  $C_5H_8CaO_6$ .

**Salts**.—(Reichardt, Vierteljahr. pr. Pharm. 19, 384, 503.)— $Na_2H_2A^{''}$ ; [100?]; hygroscopic.— $CaH_2A^{''}$ ; aq.— $Ba_2H_2A^{''}$ ; 8aq.— $BaH_2A^{''}$ ; aq.; very hygroscopic.— $MgHA^{''}$ ; aq.— $AlA^{''}$ ; yellowish-white mass.— $Fe_2H_2A^{''}$ ; 8aq.— $Pb_2C_4H_8O_{12}$  (at  $150^\circ$ ).

**Apoglucoic acid**  $C_{12}H_{22}O_{11}$  (dried at  $100^\circ$ )? Formed by boiling glucic acid with water or dilute acids or cane-sugar with dilute  $H_2SO_4$  (Mulder). Amorphous brown mass, v. sol. water, sl. sol. alcohol, insol. ether. Its alkaline salts form deep red solutions.— $PbC_{12}H_{22}O_{11}$ — $Ag_2C_{12}H_{22}O_{11}$ ; brown.— $CaC_{12}H_{22}O_{11}$  (at  $180^\circ$ ): brown amorphous mass.

**Isopoglucoic acid**. Formed by heating acetone with chlorine, potash, and HCl successively (Mulder, Z. 1868, 51).— $PbCH_2O_4$ .

**GLUCINUM** v. BERYLLIUM.

**GLUCO-COUMARIC ALDEHYDE** v. Glucoside of COUMARIO ALDEHYDE.

**GLUCODEUPOSE**  $C_{21}H_{34}O_{10}$ . The chief constituent of concretions in pears (Erdmann, A. 138, 1). Pale-yellowish grains. Insol. ordinary solvents, alkalis, cold dilute acids, and

Schweizer's solution. Split up by boiling dilute acids into glucose and dextrose  $C_6H_{12}O_6$ .

**GLUCOFERULIC ALDEHYDE** v. **FERULIC ALDEHYDE**.

**GLUCOLIGNOSE**  $C_{12}H_{22}O_{11}$ .? Occurs in pine wood (Erdmann, *A. Suppl.* 5, 223). Yellowish solid, insol. ordinary solvents, v. sl. sol. Schweizer's solution. Split up by boiling dilute HCl into glucose and lignose  $C_{12}H_{22}O_{11}$ ? (v. **CELLULOSE**).

**GLUCONIC ACID**  $C_6H_{12}O_7$ , i.e.  $CH_2(OH)(CH.OH)_4.CO_2H$ .  $[a]_D^{20} = 5.8^\circ$ .

**Formation**.—1. From glucose, cane-sugar, maltose, starch, soluble starch, and dextrin by successive treatment with bromine (or chlorine) and Ag<sub>2</sub>O (Hlasiwetz & Habermann, *A.* 155, 120; Habermann, *B.* 5, 167; *A.* 162, 297; 172, 11; Reichardt, *B.* 8, 1020; Kiliani, *A.* 205, 182; Herzfeld, *A.* 220, 342).—2. By oxidising glucose with red mercuric oxide and baryta-water (Herzfeld, *A.* 245, 32).—3. By the fermentation of glucose by mycoderma aceti in presence of CaCO<sub>3</sub> and an infusion of yeast (Boutroux, *J. Th.* 1880, 52).

**Preparation**.—1. Dextrin (30 g.) is heated in a closed vessel with bromine (60 g.) and water (500 c.c.) for 6 hours at 100°. The product is neutralised with Ag<sub>2</sub>O, filtered, freed from silver by H<sub>2</sub>S, and evaporated over the water-bath (Herzfeld, *A.* 220, 342).—2. An aqueous solution of cane-sugar is treated with bromine until the Br ceases to disappear. The HBr formed is removed by PbO, the solution is then pptd. by H<sub>2</sub>S, and the filtrate after concentration saturated with ZnCO<sub>3</sub>. The zinc-salt is subsequently decomposed by H<sub>2</sub>S (Grieshammer, *Ar. Ph.* [3] 15, 193).

**Properties**.—Unecrystallisable syrup (containing 2 aq); loses aq at 100°, and the second aq at 125°. Sol. water, insol. alcohol. Does not reduce Fehling's solution. Decomposed by alkaline hydroxides, alkaline carbonates, baryta, and lime.

**Reactions**.—1. Reduced by III and phosphorus to the lactone of oxy-*n*-hexoic acid (Kiliani & Kleemann, *B.* 17, 1296).—2. Protracted treatment with bromine forms bromoform, bromo-acetic acid, and oxalic acid.—3. Ag<sub>2</sub>O forms glycollic acid.—4. HNO<sub>3</sub> (S.G. 1.4) oxidises it to saccharic and oxalic acids.

**Salts**.—Ammonium salt: crystalline (Boutroux, *C. R.* 91, 236; 104, 359). CaA', aq (from dilute alcohol).  $[a]_D^{20} = 5.9$ . S. (of CaA') 3.8 at 16.5°.—CaA', 2 aq: groups of slender needles.—CaC<sub>2</sub>H<sub>3</sub>O<sub>7</sub>, 2 aq.—BaA', 3 aq: prisms. S. (of BaA') 3.3 at 15.5°.—BaA', 2 aq.—BaA', aq.—BaC<sub>2</sub>H<sub>3</sub>O<sub>7</sub>, 2 aq.—ZnA', 5 aq.—CdA', —PbA', —Pb<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>7</sub> (at 120°).

**Ethyl ether EtA'**. Obtained in combination with CaCl<sub>2</sub> as (EtA')<sub>2</sub>CaCl<sub>2</sub> by passing HCl into an alcoholic solution of the calcium salt. The free ether crystallises in needles.

**Penta-acetyl derivative of the ethyl ether** C<sub>2</sub>H<sub>5</sub>(OAc)<sub>5</sub>.CO<sub>2</sub>Et. [102°] (Herzfeld, *A.* 245, 32).

**Para-gluconic acid** C<sub>6</sub>H<sub>10</sub>O<sub>7</sub>.

**Preparation**.—If gluconic acid is left in contact with nitric acid (S.G. 1.3) for some time, and the solution neutralised with alkaline carbonates, salts of an isomeric paragluconic acid are obtained, and can be separated from the me-

tallic nitrate by alcohol. The free acid is a colourless syrup, of strong acid reaction, sol. water, insol. alcohol (Hönig, *M.* 1, 48). The alkaline earth salts of this acid cannot be obtained in a crystalline form, thus differing from those of gluconic acid. According to Volpert (*B.* 19, 2621) it is identical with gluconic acid.

**Salts**.—KA' (at 100°): crystalline leaflets.—NH<sub>4</sub>A' (at 100°): colourless monoclinic needles.—Pb<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>7</sub>: voluminous white ppt.

**GLUCO-PROTEINS** v. **PROTEIDS**.

**GLUCOSAMINE** v. **PROTEIDS**; *Appendix C*.

**GLUCOSAN** v. **SUGARS**.

**GLUCOSE** v. **SUGARS**.

**GLUCOSIDES**. Substances which, when decomposed by dilute acids, yield glucose (or some other sugar) and another substance not belonging to the class of carbohydrates (Laurent, *A. Ch.* [3] 36, 330). They are for the most part natural products occurring in plants. They may be viewed as compound ethers containing the group (C<sub>6</sub>H<sub>7</sub>O<sub>5</sub>), which is turned out on hydrolysis  $RC_6H_7O_5 + H_2O = RH + C_6H_7O_6$ . Some glucosides may be obtained artificially by the use of acetochlorhydric acid C<sub>2</sub>H<sub>3</sub>ClAcO<sub>2</sub>; thus helicin is formed by the action of this body upon potassium salicylaldehyde (Michael, *Ann.* 1, 308). Inasmuch as many sugars may be converted into glucose by boiling with dilute acids, the appearance of glucose after this operation does not necessarily involve the pre-existence of the residue of that particular sugar in the glucoside. The hydrolysis may be effected by boiling with dilute HCl, dilute H<sub>2</sub>SO<sub>4</sub>, baryta-water, or dilute alkalis. Some nitrogenous ferments, frequently existing in the plants themselves, can effect the hydrolysis even in the cold; e.g. emulsin in almonds, myrosin in mustard, and erythrozym in madder. The glucosides are solid, soluble in water, and usually crystalline. They give Pettenkofer's reaction with bile salts and H<sub>2</sub>SO<sub>4</sub>. The following are among the more important glucosides that yield glucose when boiled with dilute acids: arbutin, ruberythrin, salicin, daphnin, æsculin, jalapin, helleborin, turpethin, populin, bryonin, ononin, and the nitrogenous glucosides amygdalin, solanin, indican, and chitin. The following photoglucosides resemble glucosides but yield phloroglucin instead of glucose on hydrolysis: phloracetin, quercetin, and madurin. The following 'phloroglucosides' yield both phloroglucin and a sugar: phlorizin, quercitrin, robinin, and rutin.

(α)-**GLUCOSINE** C<sub>6</sub>H<sub>11</sub>N<sub>7</sub> (136°). S.G. 2 1.038. V.D. 3.81. A body formed by heating aqueous ammonia with glucose at 100° (Tanret, *Bl.* [2] 44, 103). Limpid volatile liquid. Inactive to light. —B'HCl: very deliquescent crystals. —B'EtI: pearly crystals.

(β)-**Glucosine** C<sub>6</sub>H<sub>11</sub>N<sub>7</sub> (160°). S.G. 2 1.012. V.D. 3.87. Formed by the action of ammonia on glucose at the same time as its isomeride (Tanret, *Bl.* [2] 44, 104). Liquid. The platinum-chlorides of the two glucosines are partially decomposed by boiling water (Q. de Coninck, *Bl.* [2] 45, 131).

**GLUTA CONIC ACID** CO<sub>2</sub>H.CH<sub>2</sub>.CH:CH.CO<sub>2</sub>H [132°]. (Isomeric with citraconic acid.) From di-carboxy-glutaconic ether (*g. v.*) and boiling HCl (Conrad & Guthzeit, *A.* 222, 253). White prisms. V. sol. water, alcohol, and ether. Not

decomposed below 180°. Gives no colour with  $\text{FeCl}_3$ . Sodium amalgam reduces it to glutaric acid.

**Salts.**— $\text{ZnA}''$ .— $\text{Ag}_2\text{A}''$ .

**Reference.**—CHLORO-GLUTAMIC ACID.

**GLUTAMIC ACID**  $\text{C}_5\text{H}_9\text{NO}_4$ , i.e.

$\text{C}_5\text{H}_7(\text{NH}_2)(\text{CO}_2\text{H})_2$ . [202°]. S. 1 at 15°; S. (80 p.c. alcohol) 0.7 at 15°. Occurs, probably as its amide, in pumpkin seeds (Schulze a. Barbieri, B. 11, 710, 1233), vetch seeds (Gorup-Besanez, B. 10, 780) and beet-root juice (Scheibler, B. 2, 236; Schulze, B. 10, 85; 16, 312). It may be isolated from molasses after the sugar has been removed by the strontium process (Scheibler, B. 17, 1725). Formed, together with aspartic acid, by boiling vegetable proteids with dilute  $\text{H}_2\text{SO}_4$  (Ritthausen, J. pr. 99, 454; 107, 218). Formed also by boiling casein with  $\text{HCl}$  and  $\text{SnCl}_4$  (Hasiwetz a. Habermann, A. 169, 157). Among the products of the decomposition of proteids by baryta Schützenberger (A. Ch. [5] 16, 875) found an acid  $\text{C}_5\text{H}_7\text{NO}_4$ , [150°] which formed two silver salts  $\text{AgHA}''$  and  $\text{Ag}_2\text{A}''$ , apparently not to be identified with glutamic acid.

**Preparation.**—The portion of wheat gluten that is soluble in alcohol (mucelin) is boiled for 20 hours with  $\text{H}_2\text{SO}_4$  (2½ pts.) diluted with water (6½ pts.); the product is neutralised by lime; excess of lime is removed by oxalic acid; excess of oxalic acid by lead carbonate; and excess of lead by  $\text{H}_2\text{S}$ . The strongly acid liquid yields by evaporation a crystalline mixture of tyrosine, leucine, and glutamic acid, from which, by treatment with hot water (which leaves the tyrosine undissolved), and then with alcohol of 30 p.c. (which chiefly dissolves the leucine), and recrystallisation from water with addition of animal charcoal, and from alcohol of 30 p.c., the glutamic acid is obtained pure.

**Properties.**—Trimetric tetrahedra;  $a:b:c = 801:1:179$  (Von Rath);  $\alpha = 637^\circ 85' 51''$  (Oebbecke). Sl. sol. cold water, insol. alcohol. Its solutions are acid, and have an astringent taste. In aqueous solution it is dextrorotatory,  $[\alpha]_D = 10.2$  in a 2 p.c. solution at 21°. A solution of its hydrochloride  $\text{BHCl}$  is also dextrorotatory,  $[\alpha]_D = 20^\circ$  in a 4 p.c. solution at 21°; but its neutral salts are levorotatory, thus for  $\text{CaA}''$   $[\alpha]_D = -3.7^\circ$  in a 5 p.c. solution at 22°. Its solution is not pptd. by lead acetate even on addition of ammonia. Glutamic acid does not reduce Fehling's solution. On distillation it gives pyroglutamic acid  $\text{C}_5\text{H}_7\text{NO}_3$ , and afterwards pyrrole.

**Reactions.**—1. Nitrous acid converts it into an inactive oxy-glutaric acid.—2. Baryta-water at 155° renders it inactive; but when some *Penicillium glaucum* is placed in a solution of the inactive glutamic acid it again becomes active (Schulze a. Bosshard, B. 18, 388). The inactive acid is m. sol. water (S. 1.7 at 17°).

**Salts.**—The glutamates of the alkalis and alkaline earths are v. sol. water and alcohol, and dry up to gummy masses; the copper salt is characteristic and very sparingly soluble.— $\text{HNaA}''$ .— $(\text{NH}_4)_2\text{A}''$ .— $\text{NH}_4\text{HA}''$ .— $\text{BaHA}''$ .— $\text{BaA}''$  6aq: groups of needles.— $\text{CuA}''$  2aq: S. 0.8 in the cold; 25 at 100° (Hofmeister, Sitz. W. 75, 469).— $\text{CuA}''$  2aq: blue crystalline powder (Schulze a. Bosshard, B. 16, 813).— $\text{CuA}''$  8aq:—

$\text{Ag}_2\text{A}''$  (at 100°).— $\text{H}_2\text{A}''\text{HCl}$  (at 100°): trichloro tables; sl. sol. conc.  $\text{HClAq}$ .— $\text{H}_2\text{A}''\text{HBr}$ .

**Mono-ethyl ether**  $\text{EtHA}''$ . [165°]. Crystalline, v. sol. water, sl. sol. cold alcohol, insol. ether. Alcoholic ammonia at 150° converts it into glutimide.

**Amide**  $\text{C}_5\text{H}_7\text{N}_2\text{O}_4$ , i.e.

$\text{C}_5\text{H}_7(\text{NH}_2)(\text{CO}_2\text{H})(\text{CONH}_2)$ . S. 4 at 16°. Occurs in the juice of red beet-root, from which it is isolated by precipitation with  $\text{Hg}(\text{NO}_3)_2$  (Schulze a. Bosshard, B. 16, 312). Occurs also in pumpkin-seeds (Schulze a. Barbieri, J. pr. [2] 20, 388; 32, 457). Slender white needles; v. sol. hot water; insol. absolute alcohol. Its aqueous solution is inactive, but its solution in dilute  $\text{H}_2\text{SO}_4$  or oxalic acid is dextrorotatory. Heated with acids or alkalis it gives glutamic acid.

**Imide**  $\text{C}_5\text{H}_7(\text{NH}_2) < \text{CO} > \text{NH}$ . Formed by

heating ammonium glutamate for five hours at 190°. Needles. S. 8.7 at 15.5°.— $\text{C}_5\text{H}_7\text{N}_2\text{O}_4\text{HCl}$ .— $\text{C}_5\text{H}_7\text{N}_2\text{O}_4$ .

**GLUTAMIC ACID** v. OXY-GLUTARIC ACID.

**GLUTARIC ACID**  $\text{C}_5\text{H}_8\text{O}_4$ , i.e.

$\text{CO}_2\text{H}. \text{CH}_2. \text{CH}_2. \text{CO}_2\text{H}$ . *Normal pyrotartaric acid*. *Deoxyglutaric acid*. Mol. w. 132. [98°]. (c. 300°). S. 83 at 14°. S.H. (0°-94°) 3461 (Hess, W. [2] 35, 410). Occurs as the K salt in the grease of sheep's wool (Buisine, C. R. 107, 789).

**Formation.**—1. By heating oxy-glutaric acid (1 pt.) with conc.  $\text{HIAq}$  (4 pts.) at 120° for 8 hours (Dittmar, J. pr. [2] 5, 338).—2. By the saponification of trimethylene cyanide prepared from trimethylene bromide and alcoholic  $\text{KC}_y$  (Lermontoff, B. 9, 1441; Reboul, B. [2] 25, 386; Markownikoff, A. 182, 341).—3. From  $\alpha$ -acetyl-glutaric ether (q. v.) and conc. alcoholic  $\text{KOH}$  (Wislicenus a. Limpach, A. 192, 128).—4. By heating menthol with  $\text{HNO}_3$  (20 vols.) (Moriya, C. J. 39, 78).—5. By treating glutaric acid with sodium amalgam (Conrad a. Guthzeit, A. 222, 254).—6. By heating propane tetracarboxylic acid to 180° (Kleber, A. 246, 110).—7. By boiling di-oxy-propane tri-carboxylic acid with  $\text{HIAq}$  and phosphorus (Kiliani, B. 18, 640).—8. Among the products of the oxidation of myristic acid by  $\text{HNO}_3$  (Noerdlinger, B. 19, 1898).

**Properties.**—Large transparent monoclinic prisms. V. e. sol. water, alcohol and ether. When heated with bromine and water at 120° some di-bromo-succinic acid is formed (E. Bourgoin a. Reboul, C. R. 84, 556).

**Salts.**— $\text{NH}_4\text{HA}''$ : concentric crystals.— $(\text{NH}_4)_2\text{A}''$ .— $\text{NaHA}''$  2aq.— $\text{NaA}''$  2aq.— $\text{KA}''$  4aq.— $\text{CaA}''$  4aq: stellate groups of slender needles, more sol. cold than hot water. S. 60 at 16°.— $\text{BaA}''$  6aq: small transparent needles, v. sol. water.— $\text{MgA}''$  3aq: small needles (from dilute alcohol); v. e. sol. water.— $\text{ZnA}''$ : needles. S. 1 at 18°. The solution deposits on heating characteristic minute rectangular plates with re-entering angles.— $\text{PbA}''$  4aq: heavy crystalline pp.— $\text{CuA}''$  4aq.— $\text{Ag}_2\text{A}''$ : needles (from hot water).

**Mono-ethyl ether**  $\text{EtHA}''$ . An oil formed by the action of alcohol on the anhydride in the cold (M.).

**Di-ethyl ether**  $\text{Et}_2\text{A}''$ . (237°). S.G. 1.025.

**Chloride**  $C_3H_5(COOCl)_2$ . (217°) (Reboul, *A. Ch.* [5] 14, 510).

**Anhydride**  $C_3H_4(C_2O_3)_2$ . [57°]. (c. 287°). From the silver salt and  $AcCl(M.)$ . Slender needles.

**Imide**  $C_3H_4NO_2$ . [152°]. Prepared by heating at 175°–180° the mixture of neutral and acid ammonium glutarates, obtained by neutralising glutaric acid with ammonia. Ammonia and water are given off, and the imide collects partly in the neck, partly at the bottom of the flask. The product is obtained in the pure state by crystallising from alcohol. Brilliant scales, subliming above its melting-point, sol. water and benzene, insol. ether. Its silver salt is a crystalline powder. Heated with zinc dust it forms a hydrocarbon and a basic substance, probably a hydride of pyridine. After heating with  $PCl_5$  at 60° on distilling the residue in a current of steam, a substance  $C_3H_4Cl_2N$  is obtained, crystallising in needles [60°] which appears to possess the constitution

$CH_2 \begin{matrix} \diagup CH_2 - CCl_2 \\ \diagdown CH_2 - CCl_2 \end{matrix} N$ , inasmuch as, when heated with hydriodic acid and amorphous phosphorus, it yields a substance approximately of the composition of chloropyridine (Bernheimer, *G.* 12, 281).

**GLUTAZINE** v. DI-OXY-AMIDO-PYRIDINE.

**GLUTEN** v. PROTEIDS.

**GLUTEN-FIBRIN** v. PROTEIDS.

**GLUTIC ACID** v. GLUTINIC ACID.

**GLUTIMIC ACID**  $C_5H_9NO_4$ . [180°]. One of the products of the decomposition of proteids with barium hydroxide; glistening, voluminous prisms, sparingly sol. cold water, insol. cold alcohol. A monobasic acid, forming a sparingly soluble mercuric salt (Schützenberger, *A. Ch.* [6] 16, 373).

**GLUTIN** v. PROTEIDS.

**GLUTINIC ACID**  $C_5H_9O_6$ , i.e.

$HO_2C.C(C_2H_5).CO_2H$ . [146°]. Formed by the action of alcoholic KOH upon  $\beta$ -chloro-glutamic acid  $HO_2C.CH(CCl_2CH_3).CO_2H$ ; the yield is 30–40 p.c. of the theoretical. Slender needles, v. sol. alcohol and ether, insol. benzene and chloroform. On heating the acid or its monopotassium salt with water, it is converted with evolution of  $CO_2$  into a very unstable monobasic acid, probably  $HC(C_2H_5).CO_2H$ , which gives the acetylene reactions.— $A''Pb$ : white pp.— $A''K_2$ ,  $2aq$ : long flat needles.— $A''Ba$ ,  $2aq$ : slender needles (Burton & Pechmann, *B.* 20, 148).

**GLYCERAMINE** v. GLYCIDAMINE.

**GLYCERIC ACID**  $C_3H_5O_4$ , i.e.

$CH_2(OH).CH(OH).CO_2H$ . Mol. w. 106.  $\alpha\beta$ -Di-oxy-propionic acid. Heat of neutralisation by  $\frac{1}{2}Na_2O = 11,334$ ; by  $Na_2O = 12,127$  (Gal & Werner, *Bl.* [2] 47, 163).

**Formation**.—1. By the gradual oxidation of glycerin by nitric acid (Debus, *P. M.* [4] 15, 195 & A. 109, 227; Socioff, *A.* 106, 95).—2. By the spontaneous decomposition of nitroglycerin (De la Rue & Müller, *A.* 109, 122).—3. By heating glycerin (1 mol.) with bromine (2 mols.) and a large quantity of water at 100° (Barth, *A.* 124, 341).—4. By heating  $\alpha$ -chloro- $\beta$ -oxy-propionic acid or  $\beta$ -chloro- $\alpha$ -oxy-propionic acid with moist  $Ag_2O$  (Melikoff, *C. C.* 1881, 854; *B.* 13, 272; Frank, *A.* 206, 848).—5. By heating  $\alpha\beta$ -di-bromo-

propionic acid with moist  $Ag_2O$  (Beckurts & Otto, *B.* 13, 238).—6. By heating oxy-acrylic acid  $C_3H_3O_3$  with water (Melikoff).

**Preparation**.—1. By mixing 50 g. of glycerin with 50 g. of water in a large glass tube, and adding, by means of a funnel reaching to the bottom, 50 g. of fuming nitric acid. After three or four days the contents of three such tubes are slowly evaporated on the water-bath down to about 270 g., and the syrupy mass thus obtained is preserved in a flask allowing the escape of gas, which is slowly given off. 1,620 g. of the syrupy mass are next mixed with 11 litres of water, 2,400 g. of white lead are gradually added, and the mixture is left to stand for a day. The vessel is then warmed, with constant stirring, to 61°–65°, and kept at this temperature for two hours. The liquid is decanted and allowed to deposit crystals, the mother-liquor added to the solid mass, the water lost by evaporation replaced, and the operation repeated two or three times. The lead salt thus obtained is decomposed by  $H_2S$  (Mulder, *B.* 9, 1902; cf. Beilstein, *A.* 120, 226).—2. Mercuric oxide and baryta are added to a concentrated boiling aqueous solution of glycerin. When the liquid is saturated with baryta the addition of  $H_2O$  is continued until reduction no longer takes place. The liquid is filtered, treated with  $CO_2$ , again filtered, and evaporated to a syrup, which is freed from glycerin by washing with alcohol. The residue is dissolved in water, the  $Ba$  is pptd. by the calculated quantity of  $H_2SO_4$ , and the glyceric acid which remains purified, if necessary, by means of its calcium salt. The yield is 45 p.c. of the glycerin used (Börnstein, *B.* 13, 3357).

**Properties**.—Uncrystallisable syrup; miscible with water and alcohol, insol. ether. When heated for some time at 105° it is converted into a soft, very tenacious, anhydride  $C_3H_4O_4$ ; further application of heat gives formic, acetic, pyruvic, and pyrotartaric acids and an acid  $C_6H_{10}O_8$  [83°] (Moldenhauer, *A.* 131, 323; Böttlinger, *A.* 196, 92). Distillation with  $KHSO_4$  forms pyruvic acid (Erlenmeyer, *B.* 14, 321). Glyceric acid prevents the pptn. of cupric and ferric hydrates by potash. It is optically inactive, but a solution of ammonium glycerate is rendered levorotatory by *Penicillium glaucum* (Lewkowitsch, *B.* 16, 2720).

**Reactions**.—1. Iodide of phosphorus forms  $\beta$ -iodo-propionic acid.—2. Boiling conc. KOHAq forms oxalic and lactic acids.—3. Potash-fusion gives formic and acetic acids.—4.  $PCl_5$  gives  $CH_3Cl.CHCl.COCl$  (Wichelhaus, *A.* 135, 248).

**Salts**.— $NH_4^+$ : radiating deliquescent crystals.— $KHA'$ : small crystals; the neutral K salt decomposes on evaporation.— $CaA'$ ,  $2aq$ : nodules composed of minute tables or prisms; sol. water, insol. alcohol; on adding alcohol to its aqueous solution monoglinic crystals are got.— $SrA'$ : crystals; nearly insol. cold, v. sol. hot, water (Garzaroli-Thurnlack, *A.* 182, 190).— $BaA'$ : large spherical aggregates of concentric laminae, v. e. sol. hot water, insol. alcohol.— $MgA'$ ,  $8aq$ : stellate groups of small efflorescent crystals.— $ZnA'$ ,  $aq$ : small crystals.— $CdA'$ ,  $2aq$ .— $PbA'$ .— $CuA'$ : minute sky-blue crystals, m. sol. cold water.— $MnA'$ ,  $3aq$ .— $AgA'$ : minute prisms (from water).

**Ethyl ether**  $EtA'$ . (230°–240°). S.G. 2

1-198. Formed by heating glyceric acid (1 pt.) with alcohol (4 pts.) at 175° (Henry, *B. A.* 701). Sticky liquid. A mixture of HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> converts it into its oily di-nitrate C<sub>3</sub>H<sub>5</sub>(NO<sub>2</sub>)<sub>2</sub>OEt.

*Anhydride or lactone* C<sub>3</sub>H<sub>4</sub>O<sub>3</sub>. Separates from an aqueous solution of glyceric acid evaporated at 100° and left to rest. Slender six-sided, needles (from water). Insol. alcohol and ether. It dissolves in 647 pts. of boiling water, by which it is slowly re-converted into glyceric acid.

GLYCERIC ALDEHYDE (?) C<sub>3</sub>H<sub>4</sub>O<sub>3</sub> or \*C<sub>3</sub>H<sub>4</sub>O<sub>2</sub>.

*Preparation*.—By the action of platinum black (best prepared by the method of Idrakowitsch) on glycerin mixed with double its weight of water. The mass is extracted with water, and concentrated on a water bath *in vacuo*.

*Reactions*.—Reduces Fehling's solution and ammoniacal nitrate of silver. Is coloured yellow on boiling with lime or baryta water. Becomes strongly heated when shaken with a solution of NaHSO<sub>4</sub>, after which alcohol ppts. a gummy matter, but Na<sub>2</sub>CO<sub>3</sub> or H<sub>2</sub>SO<sub>4</sub> do not set free an aldehyde from this mass. Phenyl-hydrazine hydrochloride and NaOAc gives a coloured pp.; on fractional ppn. several derivatives are obtained, none of which have been obtained pure. Of the part soluble in alkalis after a crystallisation from benzene, and one from weak alcohol, the melting-point is constant [193°]. The aldehyde ferments with yeast, but the quantity of CO<sub>2</sub> obtained is small compared to its reducing power (Grimaux, *Bl.* [2] 47, 885; cf. Renard, *C. R.* 82, 562). The same body occurs among the products of the action of nitric acid upon yeast, and it appears to be closely allied to the sugars (Grimaux, *C. R.* 105, 1175).

GLYCERIN C<sub>3</sub>H<sub>8</sub>O<sub>3</sub>, i.e.

CH<sub>2</sub>OH.CH(OH).CH<sub>2</sub>OH. *Glycerine. Glycerol.* Mol. w. 92. [20°] (Nitsche, *D. P. J.* 209, 145). (290° cor.). S.G.  $\frac{4}{3}$  1.2635 (Nicol, *Ph.* [3] 18, 302);  $\frac{4}{3}$  1.2624;  $\frac{4}{3}$  1.2598 (Parkin, *C. J.* 45, 507);  $\frac{4}{3}$  1.2590 (Brühl). M.M. 4.111 at 16° (P.). H.F.p. -1364 (Ramsey).  $\mu$  1.478.  $R_D$  33.70 (B.). S.H. 612 (Winklemann, *P.* 153, 481). *Isotonic coefficient*: 1.78 (De Vries, *Ann. Agr.* 14, 376).

Glycerin, as was first shown by Chevreul, bears the same relation to the fats and fatty oils that alcohol does to acetic ether, and is, therefore, formed from them by boiling with aqueous alkalis, baryta-water, lime-water, litharge and water, or even by heating (under pressure) with water alone. It was discovered in 1779 by Scheele, who obtained it in the preparation of lead plaster by saponifying lard with lead oxide.

*Formation*.—1. Always produced in the alcoholic fermentation of sugar, the amount being about 3 p.c. of the sugar used (Pasteur, *C. R.* 46, 867; 47, 224). Hence it occurs in all fermented liquors. Wine may contain about 1 p.c. of glycerin. Brandy also may contain a little glycerin (Morin, *C. R.* 55, 1019).—2. When *s*-tri-bromopropane CH<sub>2</sub>Br.CHBr.CH<sub>2</sub>Br is heated with AgOAc there is formed glyceryl tri-acetate or tri-acetin CH<sub>2</sub>(OAc).CH(OAc).CH<sub>2</sub>(OAc). Baryta-water converts this tri-acetin into glycerin (Wurtz, *A. Ch.* [3] 51, 87).—3. Synthetically prepared from acetone by successive conversion into isopropyl alcohol, propylene, propylene chloro-iodide, propylene chloride, and tri-chloro-propane. The tri-chloro-propane was obtained by heating

propylene chloride with iodine chloride at 140°, and was converted into glycerin by heating with water at 180° (Friedel a. Silva, *C. R.* 76, 1594).

*Preparation*.—1. By saponification with oxide of lead.—Five pts. of finely pounded litharge are heated with nine pts. of olive oil or any other glyceride and a small quantity of water, the mixture being stirred, and the water renewed till the oxide of lead is converted into a plaster; the watery liquid is then separated from this plaster, and freed from lead by a stream of H<sub>2</sub>S, and the filtrate is evaporated to a syrup over the water-bath. For many years all the glycerin of commerce was obtained by this method; but it was very apt to retain small quantities of lead, the presence of which is very objectionable in any therapeutic application of glycerin.—2. From the alkaline mother-liquor of the soap-works glycerin may be obtained by distillation with superheated steam.—3. By saponifying tallow with lime and water, ppg. excess of lime by H<sub>2</sub>SO<sub>4</sub>, and evaporating.—4. By distilling fats in a current of superheated steam at 300°; the fats are then decomposed, and the glycerin which distils over is finally rectified *in vacuo*.

*Properties*.—Thick syrup with sweet taste. Neutral to litmus. Miscible with water, alcohol, and chloroform, but insol. ether. It is slightly volatile with steam (Couttolenc, *Bl.* [2] 36, 133). Volatilisation of glycerin does not, however, take place as long as 50 p.c. of water is present, and even when there is only 26 p.c. water, mere traces of glycerin pass over (Hehner, *An.* 12, 65; cf. Nessler a. Barth, *Fv.* 21, 44; 23, 329). When distilled under atmospheric pressure it is partially decomposed, but it may be distilled under diminished pressure without decomposition. It boils at 180° under 12.5 mm. pressure (Bolas, *C. J.* 24, 84). Glycerin is hygroscopic and may absorb as much as 58 p.c. of water from the air (E. Williams, *C. C.* 1881, 76). The following table gives the specific gravity at 20° of solutions of glycerin, compared with water at 20° (Nicol, *Ph.* [3] 18, 302):—

Glycerin per cent.	Specific gravity
100 . . .	1.26348
90 . . .	1.24720
80 . . .	1.21010
70 . . .	1.18293
60 . . .	1.15561
50 . . .	1.12831
40 . . .	1.10118
30 . . .	1.07469
20 . . .	1.04884
10 . . .	1.02391

A 10 p.c. solution of glycerin freezes at -1°; a 20 p.c. solution at -2.5°; a 30 p.c. solution at -6°; a 40 p.c. solution at -17.5°; and a 50 p.c. solution at -31°. Pure glycerin may be obtained in deliquescent trimetric crystals melting at 20°: *a:b:c* = 70:1:66 (Nitsche, *D. P. J.* 209, 145; Von Lang, *P.* 162, 637). Glycerin burns with a colourless flame. Glycerin dissolves iodine. An aqueous solution of glycerin dissolves more As<sub>2</sub>O<sub>3</sub> than pure water (Schiff, *A.* 118, 86). Aqueous solutions of glycerin dissolve baryta, strontia, and lime. Pure glycerin dissolves KOH and NaOH. Glycerin dissolves all deliquescent salts, and also the sulphates of K, Na, and Cu, and the chlorides of K and Na (Pelouze, *A.* 19, 210; 20,

46). Aqueous and even dry glycerin dissolves PbO. FeCl<sub>3</sub> mixed with much glycerin is not pptd. by alkalis (*cf.* Puls, *J. pr.* 15, 83). Cupric sulphate mixed with glycerin forms, with a small quantity of potash, a pp. which dissolves in excess of potash; but on boiling the resulting deep-blue solution bluish flakes are deposited. Glycerin renders borax solution acid (D. Klein, *C. R.* 86, 826; Senior a. Lowe, *Ph.* [8] 8, 819; *C. J.* 33, 438; Donath a. Mayrhofer, *Fr.* 20, 379; Dunstan, *Ph.* [3] 13, 257).

*Tests.*—Glycerin is optically inactive, so that adulteration with sugar may readily be detected by the polariscope. The presence of glycerin in a saccharine liquid may be detected by mixing with slaked lime and sand, evaporating over a water-bath, and extracting the nearly dry residue with alcohol-ether; the alcohol-ether on evaporation leaves the glycerin behind; a borax bead after dipping in the glycerin colours a flame green (Senior a. Lowe, *C. J.* 33, 438; Donath a. Mayrhofer, *Fr.* 20, 383). If a mixture of equal volumes of glycerin, phenol, and H<sub>2</sub>SO<sub>4</sub> be heated to 120°, diluted with water, and treated with NH<sub>3</sub>, a crimson colour is developed (Reichl, *B.* 9, 1429).

*Estimation.*—1. When an aqueous solution is shaken with benzoyl chloride and sufficient NaOH to make it alkaline, an insoluble crystalline pp. is produced, which chiefly consists of the dibenzoyl-derivative C<sub>14</sub>H<sub>14</sub>(OBz)<sub>2</sub>(OH). When crystallised from petroleum-ether it forms long colourless needles [70°], v. sol. alcohol and ether, insol. water. Other hydroxylated compounds must be absent. The reaction can be used for the quantitative determination of glycerin in beverages (E. Baumann, *B.* 19, 3221; *Dw.* *H.* 11, 478).—2. Commercial glycerin (1 g.) is boiled for 1 hour with (7 g. of) Ac<sub>2</sub>O and (3 g. of) dry NaOAc in a flask with inverted condenser; the product is diluted with water (50 c.c.) and heated to boiling. In this operation the glycerin is converted into the tri-acetin, and the amount of tri-acetin can be determined after filtration by neutralisation of free acid by NaOH, saponification with standard NaOH and titration with standard HCl (Benedikt a. Cantor, *M.* 9, 521).—3. Champion and Pellet (*Bl.* [2] 19, 493) estimate the amount of glycerin in commercial samples by treatment with a mixture of nitric acid and H<sub>2</sub>SO<sub>4</sub>, the resulting nitroglycerin being dried at 100° and weighed.—4. A safer method consists in mixing the liquid (1 pt.) with lead oxide (25 pts.) and evaporating to a constant weight at 130°; the increase in weight of the lead oxide is noted (Morawski, *Fr.* 21, 130).—5. For the estimation of glycerin in wine, Macagno (*D. P. J.* 216, 95) digests a litre of the wine with recently precipitated lead hydroxide; evaporates the liquid on the water-bath, then adds a further quantity of lead hydroxide; exhausts the mass with absolute alcohol, and precipitates the dissolved lead by a stream of carbon dioxide. The filtered liquid when evaporated leaves nearly pure glycerin.—6. The estimation of glycerin in wine or beer may be effected by mixing with milk of lime and chalk, evaporating to dryness, and extracting with alcohol. The alcoholic extract is evaporated to a small bulk, mixed with alcohol-ether, filtered if necessary, dried at 105°, and weighed (Weigert, *C. C.* 1888, 1511; *cf.* Claus-

nizer, *Fr.* 20, 80). Instead of weighing the glycerin it may be oxidised either by boiling with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub>, or by heating with KMnO<sub>4</sub> and H<sub>2</sub>SiO<sub>3</sub> at 40°; in either case the amount of carbonic acid evolved or the amount of reduction effected may be noted (Legler, *An.* 12, 14; Hehner, *An.* 12, 44, 65; Planchon, *C. R.* 107, 246; Cross a. Bevan, *C. N.* 55, 9).—7. An aqueous solution of glycerin (about 25 g.) may be oxidised by KMnO<sub>4</sub> after addition of KOH (5 g.), and the oxalic acid formed pptd. as calcium salt (Fox a. Wanklyn, *C. N.* 53, 15; Benedikt a. Zsigmondy, *Fr.* 25, 587; Allen, *An.* 11, 52; Jolles, *Fr.* 27, 521).

*Reactions.*—1. Partially decomposed by distillation yielding acrolein, acetic acid, CO<sub>2</sub>, and polyglyceric compounds. When distilled with P<sub>2</sub>O<sub>5</sub> or KHSO<sub>4</sub> it yields acrolein. When distilled with CaCl<sub>2</sub> it yields acrolein, acetone, propionic aldehyde, phenol, &c. (Linnemann a. Zotta, *A. Suppl.* 8, 254; 174, 87).—2. Glycerin is oxidised by the air in presence of platinum-black to CO, and water; at the same time the so-called glyceric aldehyde (a kind of sugar) is formed. This body is fermentable by yeast (Grimaux, *Bl.* [2] 43, 251; *C. R.* 105, 1175). A substance resembling glucose is also formed by placing glycerin in contact with iron that is undergoing oxidation in moist air (Kosmann, *Bl.* [2] 27, 216).—3. Propionic and formic acids are among the products of the oxidation of glycerin in alkaline solution by ozone (Gorup-Besanez, *A.* 125, 211).—4. MnO<sub>2</sub> and HCl or H<sub>2</sub>SO<sub>4</sub> yield \*CO<sub>2</sub> and formic acid.—5. If fuming nitric acid and dilute glycerin are left in contact in two layers in the cold, gradual oxidation takes place with formation of glyceric, racemic, glycollic, glyoxylic, oxalic, formic, and hydrocyanic acids (Debus, *A.* 106, 79; Beilstein, *A.* 120, 228; Heintz, *A.* 152, 325; Przybytek, *Bl.* [2] 85, 108). By the action of HNO<sub>3</sub> on glycerin in the cold Przybytek (*Bl.* [2] 36, 145; 37, 342) also obtained an acid C<sub>4</sub>H<sub>6</sub>O<sub>8</sub>, apparently identical with saccharic acid, and inactive tartaric acid, as well as racemic acid. Werigo (*C. C.* 1881, 612) by oxidising glycerin with HNO<sub>3</sub> obtained an acid C<sub>4</sub>H<sub>6</sub>O<sub>8</sub>. On warming glycerin with dilute nitric acid (S.G. 1.18) a violent reaction ensues, and after removal of the nitrous acid with urea a liquid is obtained which reduces Fehling's solution and gives with phenyl-hydrazine hydrochloride the crystalline di-phenyl-hydrazide, 'phenyl glycerosazone' C<sub>14</sub>H<sub>14</sub>NO<sub>2</sub> or CH<sub>2</sub>(OH).C(N<sub>2</sub>HPh).CH(N<sub>2</sub>HPh) [131°] (Fischer a. Tafel, *B.* 20, 1088).—6. If lead hydroxide (500 g.) be added to boiling aqueous (85 p.c.) glycerin (1,000 g.) and, after cooling to 0°, the resulting lead compound be washed with alcohol and ether, dried at 100°, and exposed to bromine vapour, 'glycerose' is formed. It may be extracted by alcohol, and after evaporating the alcohol and treating the residue with BaCO<sub>3</sub> to remove acids, it can be dissolved in ether. Glycerose is a syrup which reduces Fehling's solution, ferments with yeast, and when treated with phenyl-hydrazine yields phenyl-glycerosazone. However, it appears to be a mixture, since it yields two oxy-acids when warmed with conc. HCl (Fischer a. Tafel, *B.* 21, 2634). If glycerin (10 pts.), Na<sub>2</sub>CO<sub>3</sub> 10 aq (35 pts.), water (60 pts.), and bromine (15 pts.) be mixed at 10° and the solution be mixed with phenyl-hydra-

sine solution two osazones are got,  $C_{11}H_{17}N_4O_6$ , [217°] and [169°] (Fischer a. Tafel, *B.* 20, 3384).—7. A mixture of  $HNO_3$  and conc.  $H_2SO_4$  gives the trinitrate, commonly called nitroglycerin.—8. Alkaline  $KMnO_4$  forms  $CO_2$ , formic acid, propionic, and traces of tartaric acid. The latter is often present as the acid manganese salt  $Mn(CO_2CH(OH)CO_2H)_2$  (Campani a. Bizzarri, *G.* 12, 1). By using strongly alkaline  $KMnO_4$ , oxalic acid (1 mol.) and  $CO_2$  (1 mol.) were obtained by Fox a. Wanklyn (*C. N.* 53, 15; cf. Planchon, *C. R.* 107, 246).—9. A solution of glycerin acidulated with 5 p.c. of  $H_2SO_4$  yields on electrolysis formic paraldehyde (tri-oxy-methylene), formic, acetic, oxalic, and glyceric acids, and a glucose (polymeride of tri-oxy-methylene) which forms a barium compound  $C_6H_7O_8BaO$ , is not fermented by yeast, and is oxidised by  $HNO_3$  to oxalic acid (Renard, *A. Ch.* [5] 17, 303). Bartoli a. Papasogli (*G.* 13, 287) obtained acrolein, formic paraldehyde, glyceric acid, and formic acid by electrolysis of glycerin.—10. Lime and  $Ag_2O$  form glycollic and formic acids (Kiliani, *B.* 16, 2415).—11. According to Dumas a. Stas (*A.* 35, 158) by gently heating glycerin with  $KOH$  it is converted into potassium formate and acetate with evolution of hydrogen. Herter (*B.* 11, 1167) also obtained lactic acid.—12. On distillation with caustic soda it is on the one hand reduced to propylene glycol, and on the other hand oxidised to formic acid; other products are methyl, ethyl, and *n*-propyl alcohol, hexylene and other hydrocarbons, acrolein, and various ketones (Belohoubek, *B.* 13, 1872; Letts, *B.* 5, 159; Fernbach, *Bl.* [2] 34, 146).—13. Distillation of the calcium derivative  $CaC_2H_5O$  gives methyl, ethyl, and hexenyl alcohols, aldehyde, acetone, di-ethyl-ketone, a ketone  $C_6H_7O$  (124°), mesityl oxide, and phorone (Destrem, *A. Ch.* [5] 27, 20).—14. By heating with bromine and water at 100° glyceric acid and bromoform are produced (Barth, *A.* 124, 841). Bromine dropped into heated dry glycerin forms acrolein. For the action of bromine and  $Na_2CO_3$ , v. Reaction 6.—15.  $HIAg$  converts glycerin into allyl iodide and propylene; an excess of  $HI$  forms isopropyl iodide (Erlenmeyer, *A.* 139, 211). When glycerin is heated with  $HCl$  mono- and di-chlorhydrins are formed, together with a crystalline compound [110°], which appears to be a polymeride of epichlorhydrin (Fauconner a. Sanson, *Bl.* [2] 43, 236).  $HBr$  forms mono- and di-bromhydrins.—16. Iodide of phosphorus  $PI_3$  forms propylene, allyl iodide, and a little allyl alcohol (Berthelot a. De Luca, *A. Ch.* [3] 43, 257; 44, 250; Henry, *B.* 14, 403). Glycerin may be conveniently converted into allyl iodide by running a solution of iodine (440 g.) in allyl iodide (160 g.) into a heated mixture of glycerin (2,000 g.), iodine (60 g.) and red phosphorus (200 g.) (Béhal, *Bl.* [2] 47, 875). Glycerin (200 g.) may also be converted into allyl iodide by mixing with iodine (135 g.), adding clear phosphorus (40 g.) cautiously and distilling in a current of  $CO_2$ . When glycerin (2 pts.) is mixed with iodine (30 pts.) and red phosphorus ( $\frac{1}{2}$  pts.) is cautiously added to the cooled mixture, isopropyl iodide is formed, and may be distilled over. Aluminium foil and iodine also form allyl iodide (Hodgkinson, *C. N.* 35, 237).—17.  $PBr_3$  and  $PBr$  form mono- and di-bromhydrin and *s*-tri-bromo-propane (Berthelot a. De

Luca, *A. Ch.* [3] 43, 304).  $PCl_3$  and  $PCl_5$  act in like manner.—18.  $S_2Cl_2$  forms di-chlorhydrin and *s*-tri-chloro-propane (Oarius, *A.* 124, 222; cf. Wolff, *A.* 150, 59).—19. When glycerin is distilled with ammonium chloride a chlorinated compound (175°) is formed, together with some acids, and a base 'glycoline'  $C_6H_{11}N_2$  (155°). S.G. 1.008. This base forms a platinumchloride  $B''H_2PtCl_6$ , a deliquescent crystalline hydrochloride  $B''HCl$ , and a crystalline ethyl-iodide  $B''EtI$  (Étard, *C. R.* 92, 795).—20. When glycerin is heated with acids one or more acid radicles usually displace its hydroxylic hydrogen. Thus acetic acid forms the acetins, citric acid forms the citrins, phosphoric acid forms glycerophosphoric acid, sulphuric acid gives glycerosulphuric acid.—21. Excess of oxalic acid is split up by glycerin at 100° into formic acid and  $CO_2$  (Berthelot, *A.* 98, 139). When excess of glycerin is heated with oxalic acid at 200°–250° it is reduced to allyl alcohol (Tollens, *A.* 156, 130). Distillation with formic acid also converts glycerin into allyl alcohol (Hennfinger, *Bl.* [2] 21, 242).—22. When glycerin is distilled with citric acid there is formed glycidic pyruvate  $CH_2CHCH_2O.CO.CO.CH_3$  [82°]

(241°) (De Clermont a. Chautard, *C. R.* 105, 520). 23. Distillation with  $Na_2S$  gives an oil (58°) whence  $HgO$  gives a crystalline compound [35°] (Schlagdenhauffen, *C. R.* 76, 1021).—24. Heated with anhydrous borax it forms  $NaBO_2$  and the borin  $C_3H_7BO_2$  which is decomposed by water into boric acid and glycerin (Dunstan, *Ph.* [3] 14, 41).—25. Glycerin acts upon benzoic aldehyde at 200°, forming benzylidene-glycerin

a liquid that is not volatile under atmospheric pressure, but boils under 20 mm. pressure at 190°–200° (Harnitz-Harnitzky a. Menschutkin, *A.* 136, 127; *Bl.* [2] 8, 253). In a similar manner it reacts with acetic aldehyde, forming

(184°–188°), S.G. 2 1.081, V.D. 4.162; and with valeric aldehyde forming amylidene glycerin (224°–228°), S.G. 2 1.027, V.D. 5.526 (calc. 5.544).—26. Glycerin in dilute solution undergoes fermentation (due to *Bacillus butylicus*?) in presence of chalk forming *n*-butyl alcohol, *n*-ethyl alcohol, *n*-propyl alcohol, *n*-amyl alcohol (138°), trimethylene glycol, hexoic, butyric, lactic, and acetic acids, and evolving  $CO_2$  and hydrogen (Fitz, *B.* 9, 1348; 10, 276; 11, 42; 13, 36, 131; 15, 876; Morin, *C. R.* 105, 818; cf. Berthelot, *A. Ch.* [3] 49, 846; Bechamp, *Z.* [2] 5, 603; Hoppe-Seyler, *H.* 3, 353; *C. J.* 40, 82; Freund, *M.* 2, 638).—27. Distillation of glycerin (1 kilo.) with *rinco-dust* (2 kilos.) yields propylene, acrolein, allyl alcohol, hexenyl alcohol  $C_6H_{11}O$  (c. 140°), and a compound  $C_{12}H_{22}O_2$  (c. 200°) (Kerstein, *B.* 9, 695; Claus, *B.* 18, 2931).—28. Distillation with calcium chloride gives a liquid  $C_6H_{11}O$ , (172°) formerly called glyceryl oxide, but which appears rather to be the anhydride of acetyl-carbinol  $(CH_3.CO.CH_2)_2O$ . The same liquid is found in the black residue in the preparation of allyl

alcohol from glycerin and oxalic acid. It may be reduced by HI to glycerin. It is miscible with water, alcohol, and ether. Water at 100° converts it into glycerin. Br forms dibromhydrin. Sodium-amalgam does not attack it. Chromic acid mixture gives formic acid and acetic aldehyde. Hot dilute HCl converts it into a substance that reduces Fehling's solution and ammoniacal AgNO<sub>3</sub> (Linnemann a. Von Zotta, *A. Suppl.* 8, 264; Von Gegerfelt, *B.* 4, 919; Zotta, *A.* 174, 87; Tollens, *Z.* 1871, 528; Tollens a. Loe, *B.* 14, 1947; Silva, *C. R.* 93, 418). 29. *Aniline, nitro-benzene*, and H<sub>2</sub>SO<sub>4</sub> form quinoline (Skrap, *M.* 2, 139; 8, 381).—30. *Acetamide* and P<sub>2</sub>O<sub>5</sub> give (*Py.* 2)-methyl-pyridine (Zanoni, *B.* 15, 528).—31. Heated with *ammonium sulphate* at 255° for seven hours there is formed a mixture of bases of the pyridine series, including pyridine, (*Py.* 2)-methyl-pyridine, and a di-methyl-pyridine (Storch, *B.* 19, 2456, cf. *Reaction* 19).—32. By heating with aniline and ZnCl<sub>2</sub> it forms skatole (O. Fischer a. German, *B.* 16, 710).—33. Growing *algæ* (*Spirogyra*) are capable of converting glycerin into starch (Bokorny, *C. O.* 1888, 858).

**Metallic derivatives.**—The heat developed by the action of alkalis upon glycerin has been studied by De Forcrand (*C. R.* 103, 596; 104, 116, 291, 861; 106, 665, 746; 107, 269). NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>. Obtained by heating glycerin with sodium-amalgam or with NaOEt. Prepared by adding glycerin to an alcoholic solution of NaOEt, when radiating stars composed of minute crystals of NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOEt separate (the ppn. is exothermic, but the ppn. of C<sub>2</sub>H<sub>5</sub>NaO, would have been endothermic); when these crystals are heated in a current of dry hydrogen they give off their alcohol of crystallisation (Letts, *C. J.* 25, 450; Blaas, *M.* 2, 785). White deliquescent powder, decomposed by water into NaOH and glycerin. CS<sub>2</sub>, heated with it at 55° forms NaS.CS.O.C<sub>2</sub>H<sub>3</sub>(OH)<sub>2</sub>; an orange mass, insol. ether, decomposing at 66°, and crystallising from alcohol with HOEt (Löbisch a. Looss, *M.* 2, 372). Glycerin (1 mol.) mixed with a concentrated solution of NaOMe in MeOH deposits NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOME in deliquescent needles, which give off MeOH in a stream of hydrogen at 120°. The corresponding NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOEt, NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOCH<sub>2</sub>Pr, and NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOCH<sub>2</sub>Et, may be obtained in like manner (De Forcrand, *C. R.* 104, 291). Sodium-glycerin and methylene chloride form syrupy (CH<sub>2</sub>(OH).CH(OH).CH<sub>2</sub>O).CH<sub>2</sub> (Holand, *A.* 240, 242). Na<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>4</sub> [220°]. When NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> is mixed with alcoholic NaOEt and evaporated at 100° to 120° in hydrogen the residue is NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·NaOEt, but at 180° the di-sodium derivative Na<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>4</sub> is left (Löbisch a. Looss, *M.* 2, 843; De Forcrand, *C. R.* 106, 665). Deliquescent crystalline mass; readily decomposed by moist air. The compound Na<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>4</sub> has not been obtained.—KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOEt: laminae.—KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>: obtained in the same way as the corresponding Na derivative (De Forcrand, *C. R.* 104, 116). Does not react with KOMe even at 180°. —KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOME. —KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOPr. —KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>·HOCH<sub>2</sub>Et.—BaC<sub>2</sub>H<sub>3</sub>O<sub>4</sub>. Prepared by heating glycerin with BaO at 50° (Destrem, *C. R.* 90, 1218; *A. Ch.* [5] 27, 17, 44). White deliquescent powder, turning yellow in dry air;

decomposed by water into baryta and glycerin. On distillation it gives hydrogen, BaCO<sub>3</sub>, methane, propylene, and various alcohols of the series C<sub>2</sub>H<sub>5</sub>O.—CaC<sub>2</sub>H<sub>3</sub>O<sub>4</sub>. Prepared in the same way as the preceding which it resembles in physical properties. Decomposed on distillation into aldehyde, acetone, di-ethyl-ketone, mesityl oxide, phorone, methyl alcohol, ethyl alcohol, and hexenyl alcohol (D.).—Pb(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>, formed by mixing a hot solution of Pb(OAc)<sub>2</sub> (22g.) in water (250 c.c.) with glycerin (20 g.) and KOH (15g.). Slender needles.—Pb<sub>2</sub>(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>3</sub>. A sticky pp. formed by boiling 50 grms. of lead acetate with 250 c.c. water and 25 grms. of PbO, filtering and mixing with 75 grms. of glycerin (S.G. 1.24) and a solution of 20 g. KOH (in 100 c.c. water) which has been boiled with excess of PbO.—2(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>Pb.PbNO<sub>3</sub>), Pb(OH)NO<sub>3</sub>. Formed by adding NH<sub>3</sub> (2.57 grms.) to a solution of lead nitrate (25 grms.) and glycerin (30 grms.) in water (250 c.c.) (T. Morawski, *J. pr.* [2] 22, 408). Na<sub>2</sub>Mn(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>. Formed by boiling hydrated MnO<sub>2</sub> (from Mn(OAc)<sub>2</sub> and chlorine) with glycerin and aqueous NaOH (Schottländer, *A.* 155, 230). Yellowish-red mass, insol. alcohol and ether, v. sol. aqueous glycerin. Boiling water decomposes it with ppn. of hydrated MnO<sub>2</sub>. Its solution gives pps. with AgNO<sub>3</sub>, with Pb(NO<sub>3</sub>)<sub>2</sub>, and with Hg<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>.—SrMn(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>. Obtained by dissolving strontium hydroxide (12 pts.) in glycerin (150 pts.) and adding ppd. hydrated manganese dioxide (3 pts.) to the boiling solution. Light ochre-yellow powder.

**Glycerin mono-nitrate** C<sub>2</sub>H<sub>3</sub>NO, i.e. C<sub>2</sub>H<sub>3</sub>(OH)<sub>2</sub>(ONO<sub>2</sub>). From glycerin and HNO<sub>3</sub>, diluted with (3 pts. of) water (Hanriot, *A. Ch.* [5] 17, 118). Liquid, v. e. sol. water, sl. sol. ether. Explodes when struck.

**Glyceryl tri-nitrate** C<sub>2</sub>H<sub>3</sub>(ONO<sub>2</sub>)<sub>3</sub>. **Nitro-glycerin**. [−20°]. S.G. 1.60 at 15° S. −0.125; S. (alcohol) 42; S. (MeOH) 125 Mol. v. 227. Prepared by dropping glycerin (dried at 100°) into a mixture of fuming HNO<sub>3</sub> and conc. H<sub>2</sub>SO<sub>4</sub> kept below 10°. After some hours the product is poured into water, and the ppd. nitroglycerin dried at 70° (Sobrero, *A.* 64, 398; Williamson, *A.* 92, 305; Boutmy a. Faucher, *Bl.* [2] 27, 383; Matthew Hay, *Tr. E.* 32, 67). Viscid liquid, without odour (when cold) but with sweet taste. Almost insol. water, v. sol. alcohol, ether, chloroform, HOAc, benzene, and phenol; nearly insol. glycerin. Solidifies in a freezing mixture in long needles. Poisonous. When quite pure it may be kept for any length of time, otherwise it gradually decomposes forming glyceric, oxalic, and nitrous acids (De la Rue a. Müller, *A.* 109, 122). When struck it explodes violently. A mixture of nitroglycerin with silica in the form of infusorial earth is called dynamite (Nobel, *D. P. J.* 90, 144). **Reactions.**—1. Alcoholic potash forms nitrite, nitrate, acetate, oxalate, and formate of potassium, a reddish-brown resinous mass, and a substance which when dissolved in even 30 volumes of hot alcohol forms a jelly when cold (Hay).—2. **Alkaline carbonates** produce the same quantity of nitrous acid (containing 33 p.c. of the nitrogen) as alcoholic KOH. Ammonia acts in like manner but less energetically. Na<sub>2</sub>HPO<sub>4</sub> behaves like NH<sub>3</sub>.—3. HClAq decomposes it, as does hot (but not cold) H<sub>2</sub>SO<sub>4</sub>.

4.  $\text{HIAg}$  decomposes nitro-glycerin into glycerin and  $\text{NO}$  (Mills, *J.* 1864, 494).—5. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{Hg}$  also give off  $\text{NO}$  by the measurement of which the nitro-glycerin might be estimated (Hempel, *Fr.* 20, 86; Hess, *Fr.* 22, 128).—6. When evaporated with yellow ammonium sulphide it is reduced to glycerin (Bloxxam, *C. N.* 47, 169).

**Glyceryl tri-nitrite**  $\text{C}_3\text{H}_5(\text{NO}_2)_3$ . (c.  $150^\circ$ ). S.G.  $\frac{10}{15^\circ}$  1.291. **Formation**.—1. Dry nitrous acid gas from  $\text{As}_2\text{O}_3$  and  $\text{HNO}_3$  (S.G. 1.35) passed into cold glycerin forms two layers, the smaller is an aqueous solution of nitrous acid, the larger is impure glyceryl trinitrite  $\text{C}_3\text{H}_5(\text{ONO})_3$ . It is purified by distillation in a current of hydrogen (O. Masson *C. J.* 43, 348). **Properties**.—Boils at about  $150^\circ$  with partial decomposition. Yellowish oil. Burns with whitish flame, does not explode when struck. Bleaches the skin. Sol. ether, chloroform and benzene, but insol.  $\text{CS}_2$ . With cold glacial acetic acid, it forms a green solution which gives off nitrous fumes when heated. It decomposes spontaneously giving off  $\text{NO}$ . **Reactions**.—1.  $\text{H}_2\text{SO}_4$  violently decomposes it.—2.  $\text{K}_2\text{CO}_3$  forms  $\text{KNO}_3$ . 3. Alcohol forms  $\text{EtONO}$ .—4. It does not mix with water, but is slowly decomposed by it, glycerin and  $\text{HNO}_3$  being apparently formed in the first instance.

**Glycero-sulphuric acids**—

**Mono-sulphuric**  $\text{C}_3\text{H}_5(\text{OH})_2\text{SO}_3\text{H}$ . **Glycerin-sulphuric acid**. From glycerin (1 pt.) and sulphuric acid (2 pts.) (Pelouze, *A. Ch.* 63, 21). Unstable liquid, being decomposed by evaporating its solution even below  $0^\circ$ . It decomposes carbonates forming salts which are v. sol. water and very unstable.— $\text{CaA}'$ : needles, begins to decompose at  $140^\circ$ , giving off acrolein, acrylic acid, and  $\text{SO}_2$  (Redtenbacher, *A.* 47, 118).

**Di-sulphuric**  $\text{C}_3\text{H}_5(\text{SO}_3\text{H})_2(\text{OH})$ . Formed by slow action of water on the tri-sulphur which it much resembles (Claesson, *J. pr.* [2] 20, 6).

**Tri-sulphuric**  $\text{C}_3\text{H}_5(\text{SO}_3\text{H})_3$ . **Glyceryl tri-sulphuric acid**. Formed by adding glycerin slowly to chloro-sulphuric acid ( $\text{ClSO}_3\text{H}$ ) as long as  $\text{HCl}$  is briskly given off. The crystals obtained are dried over  $\text{H}_2\text{SO}_4$  (Claesson, *J. pr.* [2] 20, 4). Slowly decomposed by water:  $\text{C}_3\text{H}_5(\text{SO}_3\text{H})_3 + \text{H}_2\text{O} = \text{C}_3\text{H}_5(\text{SO}_3\text{H})_2(\text{OH}) + \text{H}_2\text{SO}_4$ . Boiling water decomposes it into glycerin and sulphuric acid.— $\text{BaA}'$ .

**Glycero-phosphoric acid**  $\text{C}_3\text{H}_5\text{PO}_4$ , i.e.  $\text{C}_3\text{H}_5(\text{OH})_2\text{O.P.O}(\text{OH})_2$ . Exists in small quantity in human urine (Sotnitschewsky, *H.* 4, 214). Obtained from lecithin or the yolk of eggs by boiling with aqueous alkalis or baryta (Gobley, *J. Ph.* [3] 9, 161; Strecker, *C. R.* 52, 1270). Formed by heating glycerin with  $\text{H}_3\text{PO}_4$  or  $\text{P}_2\text{O}_5$  (Pelouze, *C. R.* 12, 718). The free acid is decomposed by evaporation of its aqueous solution.

**Salts**.— $\text{BaA}$  (Thudichum a. Kingzett, *C. J.* 30, 20).— $\text{BaA}''$  aq.— $\text{CaA}$ — $\text{CaH}_2\text{A}''$ — $\text{PbA}''$ : insol. water.

**Di-stearyl-glycero-phosphoric acid**  $\text{C}_3\text{H}_5(\text{O.C}_2\text{H}_4\text{H}_7\text{O})_2\text{O.P.O.H}$ . [ $56^\circ$ – $63^\circ$ ]. Obtained by heating di-stearin with  $\text{P}_2\text{O}_5$  at  $110^\circ$ . The product is treated with alcohol 85 (p.c.). The residue is extracted with boiling alcohol and filtered; powdered  $\text{Na}_2\text{CO}_3$  is added to the filtrate when a mixture of sodic phosphate and sodic di-

stearyl-glycerophosphate is ppd. This is extracted with hot benzene which dissolves the latter. A mixture of glacial acetic acid and  $\text{H}_2\text{SO}_4$  liberates the free acid from its sodium-salt (Hundeshagen, *J. pr.* [2] 28, 235). Fat-like mass. Beddens moist litmus. The fused acid swells up when moistened. Sl. sol. hot water and dilute acetic acid, insol. dilute mineral acids, v. sol. aqueous alkalis, glacial acetic acid, alcohol, ether, benzene, and benzoline. Separates from hot solutions in a paste-like mass of small needles. Heated with dilute acids or alkalis it gives glycerin, stearic acid, and phosphoric acid. The ammonium salt is decomposed by heat into  $\text{NH}_3$  and the free acid. The sodium salt melts about  $180^\circ$ ; on cooling it solidifies to a glassy mass which swells up in warm water forming a mass of globules resembling the myeline condition of lecithin.

Chloride  $\text{C}_3\text{H}_5(\text{O.C}_2\text{H}_4\text{H}_7\text{O})_2\text{O.P.O.Cl}$ . [ $24^\circ$ ]. From di-stearin (4 pts.) and  $\text{POCl}_3$  (1 pt.); the product being extracted with ether. The ether is then mixed with alcohol, filtered, and placed over  $\text{H}_2\text{SO}_4$  and  $\text{KOH}$ . Wedge-shaped plates. V. sol. alcohol, ether, and benzene. Decomposes at  $100^\circ$ , forming stearic acid. Water soon decomposes it into stearic acid, glycerophosphoric acid, and  $\text{HCl}$ .

**Neurine salt**

$\text{C}_3\text{H}_5(\text{O.C}_2\text{H}_4\text{H}_7\text{O})_2\text{O.P.O}(\text{OH}).\text{ONMe}_2\text{C}_2\text{H}_4\text{OH}$ . Prepared by digesting di-stearyl-glycerophosphoric acid with an alcoholic solution of the proper quantity of neurine carbonate. Waxy mass. Sol. alcohol. Swells up in warm water, forming round globules like the myeline form of lecithin. An alcoholic solution of  $\text{PtCl}_2\cdot 2\text{HCl}$  gives a pp. of neurine platino-chloride only. Lecithin (*q. v.*), on the other hand, gives a platino-chloride of its own under similar conditions.

**Formyl derivative**  $\text{C}_3\text{H}_5(\text{OH})_2(\text{OCHO})$ .

**Monoformin**. Formed by heating glycerin with oxalic acid at  $190^\circ$  (Tollens a. Henninger, *Bt.* [2] 11, 395). Formed also by the action of monochlorhydrin upon sodium formate at  $160^\circ$  (Van Romburgh, *R. T. C.* 1, 186). Decomposed on distillation into  $\text{CO}$ , water, and allyl alcohol.

**Di-formyl derivative**  $\text{C}_3\text{H}_5(\text{OH})(\text{OCHO})_2$ .

**Diformin**. (c.  $165^\circ$  at 20 mm.). S.G.  $\frac{14}{15^\circ}$  1.304. may be extracted by ether from the residue obtained in preparing formic acid by distilling anhydrous oxalic acid with glycerin (Van Romburgh, *C. R.* 93, 847). Liquid, sol. alcohol, ether, and chloroform, insol.  $\text{CS}_2$ . Inactive to light. Decomposed by water into formic acid and glycerin. Decomposed by distillation into water,  $\text{CO}$ , and allyl formate. When heated with anhydrous oxalic acid it gives off  $\text{CO}$  and formic acid, and may therefore be an intermediate product in the preparation of formic acid. When heated with glycerin (6 pts.) at  $220^\circ$  it gives  $\text{CO}$ ,  $\text{CO}_2$ , and allyl alcohol.

**Mono-acetyl derivative**  $\text{C}_3\text{H}_5\text{O}$ , i.e.  $\text{C}_3\text{H}_5(\text{OH})(\text{OAc})$ . Mol. w. 134. S.G. 1.20.

Obtained by heating a mixture of equal volumes of glycerin and glacial acetic acid at  $100^\circ$  for a long time (Berthelot, *A. Ch.* [3] 41, 277; Berthelot a. De Luca, *A. Ch.* [3] 52, 433). Neutral liquid, having a faint ethereal odour. Miscible with ether. When mixed with half its bulk of water it forms a clear liquid, which becomes turbid on

addition of a larger quantity of water, by which it is partially decomposed. With alcohol and HCl it yields glycerin and acetic ether.

*Di-acetyl derivative*  $C_8H_{16}O_4$ , i.e.  $C_2H_5(OH)(OAc)_2$ . *Diacetin*. Mol. w. 176. (280°). S.G.  $^{25}$  1.184. Formed by heating glycerin (1 pt.) with glacial acetic acid (4 or 5 pts.) at 200°. Liquid; becomes viscous at -40°. Scarcely attacked by  $AcCl$  (Hubner a. Müller, Z. 1870, 344).

*Di-acetyl derivative*  $C_8H_{16}(OH)(OAc)_2$ . (252°). S.G.  $^{25}$  1.148. From epichlorhydrin and  $AgOAc$  (Lauter, J. 1876, 343).

*Triacetyl derivative*  $C_{10}H_{18}O_6$ , i.e.  $C_3H_7(OAc)_3$ .

*Triacetin*. *Glycerol triacetate*. Mol. w. 218. (268° i. v.). S.G.  $^{25}$  1.174. S. 28, at 27°. Occurs in some fats, as in the oil from the seed of the spindle-tree (*Euonymus europaeus*) (Schweizer, J. pr. 63, 437). Formed by heating diacetin with glacial acetic acid (18 pts.) for 3 hours at 250°. Formed also by heating  $\beta$ -tri-bromo-propane with  $AgOAc$  (Wurtz, A. 102, 339). Prepared by boiling glycerin (150 pts.) with  $HIOAc$  (300 pts.) for 40 hours, fractionally distilling the product, dissolving in water, and extracting with ether (H. Schmidt, A. 200, 99). The rate of etherification of glycerin by acetic acid has been studied by Menschutkin (B. 13, 1814). Liquid, sol. dilute alcohol and ether.

*Mono-butyryl derivative*  $C_8H_{16}O_4$ , i.e.  $C_2H_5(OH)_2(O.CO.Pr.)$ . S.G.  $^{25}$  1.088. S. 267. From butyric acid and glycerin by heating for 3 hours at 200° (Berthelot, A. Ch. [3] 41, 261). Neutral liquid; mixes with  $\frac{3}{4}$  vol. of water, but on adding more water the solution becomes turbid. Decomposed by alkalis and alkaline earths into glycerin and butyric acid. Alcohol and HCl yield butyric ether and glycerin.

*Di-butyryl derivative*  $C_8H_{16}(OH)(O.CO.Pr.)_2$ . (320°). S.G.  $^{25}$  1.083. Formed by heating glycerin with butyric acid for several hours at 275°. Liquid. Not solid at -40°. Aqueous  $NH_3$  decomposes it, forming butyramide.

*Tri-butyryl derivative*  $C_{12}H_{22}(O.CO.Pr.)_3$ . (235°). S.G.  $^{25}$  1.052. Occurs in butter, along with other glycerides. Obtained by heating mono-butyryl (1 pt.) with butyric acid (15 pts.) at 240° for 4 hours (Berthelot). Formed also by boiling glycerin (1 mol.) with butyric acid (3 mols.) for 60 hours (Lebedeff, H. 6, 150). Oil, v. sol. alcohol and ether.

*Mono-valeryl derivative*  $C_8H_{16}(OH)(O.CO.C_2H_5)$ . S.G.  $^{25}$  1.100. Formed by heating valeric acid with excess of glycerin for 3 hours at 200°. Mixes with half its bulk of water, but the solution becomes turbid on further addition of water. Alcohol and HCl form valeric ether and glycerin.  $NH_3Aq$  gives valeramide.

*Di-valeryl derivative*  $C_{10}H_{18}(OH)(O.CO.C_2H_5)_2$ . S.G.  $^{25}$  1.059. From glycerin and valeric acid at 275°. Oil, with fishy odour. Becomes semi-solid at -40°.

*Tri-valeryl derivative*  $C_{14}H_{26}(O.CO.C_2H_5)_3$ . From glycerin (1 pt.) and valeric acid (9 pts.) at 220°. Oil; sol. alcohol and ether. Occurs in the oil of *Delphinus globiceps* (Chevreul).

#### *Mono-benzoyl derivative*

$C_9H_9(OH)_2(OBz)$ . *Benzoin*. S.G.  $^{16.5}$  1.228. Formed by heating benzoic acid with excess of glycerin at 200° (Berthelot, A. Ch. [3] 41, 290). Thick viscous oil, insol. water, sl. sol.  $CS_2$ , v. sol. alcohol and ether. Decomposes at 320°, giving off acrolein and benzoic acid.

*Di-benzoyl derivative*  $C_{18}H_{18}(OH)(OBz)_2$ . [70°]. From glycerin,  $BzCl$ , and dilute  $NaOH$  (E. Baumann, B. 19, 3221). Long needles (from ligroin); insol. water, v. e. sol. alcohol and ether.

*Tri-benzoyl derivative*  $C_{27}H_{27}(OBz)_3$ . *Tribenzoin*. [74°]. S.G.  $^{25}$  1.228. Obtained by heating benzoic acid with benzoic acid (12 pts.) for 4 hours at 280° (B.). Formed also by heating epichlorhydrin with  $HOBz$ ; or from epibromhydrin and  $KOBz$  at 200° (Van Romburgh, R. T. C. 1, 46, 143). Large needles (from ether). V. e. sol. ether, v. sol. boiling alcohol, sl. sol. ligroin.

#### *o-Oxy-benzoyl derivative*

$C_9H_7(OH)_2(O.CO.C_6H_4.OH)$ . S.G. 1.1366. From salicylic acid, glycerin, and HCl at 100° (Göttig, B. 10, 1817). Colourless liquid; v. sol. alcohol, ether, and  $CS_2$ .

*Benzoyl-succinic derivative*  $C_{11}H_{14}O_4$ , i.e.  $C_2H_5(C_6O_5)_2O_2C_2H_5.OBz$ . *Benzosuccinin*. Formed by heating glycerin with benzoic and succinic acids at 200° (Van Bemmelen, J. pr. 69, 84). Soft mass, decomposed by boiling water or alcohol, more readily by alkalis, into glycerin, benzoic acid, and succinic acid.

*Tri-myristyl derivative*  $C_{48}H_{98}O_6$ , i.e.  $C_{12}H_{25}(O.C_4H_9)_3$ . [55°] (Masino, A. 202, 179); [46°] (in Otoba). Occurs in nutmegs (from *Myristica moschata*), from which it may be extracted by ether (Playfair, A. 37, 155; Comar, J. 1859, 366; Cimento, 9, 185). Occurs also in otoba, a fatty substance derived from *Myristica Otoba* (Uricachea, A. 91, 369). Crystallises from ether in laminae. Split up by boiling alkalis into glycerin and myristic acid.

*Mono-palmityl derivative*  $C_{26}H_{52}O_4$ , i.e.  $C_2H_5(OH)_2(O.C_{15}H_{31})$ . *Monopalmitin*. [58°] (B.); [63°] (C. a. S.). S. (alcohol) 5.360 at 22.5°. Obtained by heating a mixture of glycerin and palmitic acid for 24 hours at 200°; the product is shaken with lime-water and extracted with ether, from which tripalmitin separates first, then dipalmitin, and finally monopalmitin (Berthelot; Chittenden a. Smith, Am. 6, 225). Radiating prisms; may be distilled *in vacuo*, but is decomposed when heated under atmospheric pressure, yielding acrolein and other products.

*Di-palmityl derivative*  $C_{52}H_{104}O_6$ , i.e.  $C_2H_5(OH)(O.C_{15}H_{31})_2$ . *Dipalmitin*. [50°] (B.); [61°] (C. a. S.). S. (alcohol) 2.10 at 20°. Formed by heating palmitic acid with glycerin for 14 hours at 100° (B.). Tables or needles. Like the other palmitins, it is rapidly saponified by water and  $PbO$  at 100°.

*Tri-palmityl derivative*  $C_{78}H_{156}O_9$ , i.e.  $C_2H_5(OC_{15}H_{31})_3$ . *Tripalmitin*. Mol. w. 806. [62°]. S. (alcohol) 0.043 at 21°. Occurs in those natural fats that yield palmitic acid on saponification (v. Fats and Acids). Obtained from palm oil by expressing the liquid portion, washing the residue with boiling alcohol, and crystallising it from ether (Stenhouse, A. 86,

54). It may be formed by heating monopalmitin (1 pt.) with palmitic acid (10 pts.) for 28 hours at 250° (Berthelot). Crystalline mass, v. sl. sol. alcohol, v. e. sol. ether. According to Duffy (C. J. 5, 197) some varieties of natural palmitin melt at 46°.

*Mono-stearyl derivative*  $C_{24}H_{48}O_2$ , i.e.  $C_{21}H_{41}(OH)(OC_{23}H_{45}O)$ . *Monostearin*. [62°]. Prepared by heating stearic acid with excess of glycerin at 220° as long as the former increases in volume. The upper layer is recrystallised from alcohol and ether (Berthelot, A. Ch. [3] 41, 221; F. Hundeshagen, J. pr. [2] 28, 226). Dendritic groups of needles. Readily soluble in warm alcohol and ether. May be distilled *in vacuo*. Easily saponified by alcoholic potash. Gives off acrolein when strongly heated.

*Di-stearyl derivative*  $C_{48}H_{96}O_4$ , i.e.  $C_{21}H_{41}(OH)(OC_{23}H_{45}O)_2$ . *Di-stearin*. [77°]. S. (alcohol) 7 at 78°. Prepared by heating monostearin with the calculated quantity of stearic acid at 180° as long as water is evolved. Crystallised from alcohol and then from benzoline (Berthelot; Hundeshagen). Clumps of glittering plates (from alcohol); or small spheroids, formed of radiating clusters of minute needles (from ether, ligroin, benzene, and  $CHCl_3$ ). Saponified by alcoholic KOH. Metallic derivatives. —  $C_{24}H_{48}O_2(C_{23}H_{45}O)_2ONH_4$ . From  $NH_3$  and an ethereal solution of di-stearin. —  $C_{24}H_{48}O_2(C_{23}H_{45}O)_2ONa$ . Acetyl derivative. —  $CH_3CO_2(C_{23}H_{45}O)_2Ac$ . [30°].

*Tri-stearyl derivative*  $C_{72}H_{144}O_6$ , i.e.  $C_{21}H_{41}(OC_{23}H_{45}O)_3$ . *Tristearin*. *Stearin*. [55°] and [72°]. S.G. (liquid) .925 at 66°. Occurs in many fats, especially in the solid tallow and lards from animals (Chevreul, *Recherches sur les corps gras*; Braconnot, A. Ch. 93, 225; Vogel, A. Ch. 58, 154; Lecanu, A. 12, 25; Liebig a. Pelouze, A. 19, 264; Redtenbacher, A. 35, 195; Francis, A. 42, 254; Arzböcher, A. 70, 239; Heintz, P. 84, 221; Duffy, C. J. 5, 197, 303; Berthelot, *Chimie Organique*, 2, 52; A. Ch. [3] 41, 216, 432; 47, 297; Kopp, A. 93, 194; Bouis, C. R. 45, 35; Bouis a. Pimentel, C. R. 44, 1355). It is very difficult to free stearin from palmitin by fractional crystallisation, but it may be obtained from the fat of the seeds of *Brindonia indica*. Best prepared in a pure state by heating monostearin (1 pt.) with stearic acid (18 pts.) at 270° for 3 hours (Berthelot); or by heating glycerin with stearic acid for 24 hours at 200° (Heintz, A. 92, 300). Pearly nodules or laminae and slender needles. V. sl. sol. cold alcohol, v. sol. boiling alcohol, v. e. sol. ether. Has no taste or odour. May be distilled *in vacuo*. When heated it melts at 56°, but when further heated it becomes solid again, and finally melts at 72°. These two melting-points are lowered by impurities, thus when the stearin has been prepared from fats they may be 52° and 62° respectively. According to Duffy this phenomenon may be explained by assuming the existence of three modifications of stearin.

*Arachyl derivative*  $C_{26}H_{50}O_2$ , i.e.  $C_{23}H_{43}(OH)(OC_{23}H_{45}O)$ . From arachic acid and glycerin (Berthelot, A. Ch. [3] 47, 355). Granules, v. sl. sol. cold ether.

*Di-arachyl derivative*  $C_{52}H_{100}O_4$ , i.e.  $C_{23}H_{43}(OH)(OC_{23}H_{45}O)_2$ . [75°]. Slender grains. V. sl. sol. cold ether.

*Tri-arachyl derivative*  $C_{78}H_{150}O_6$ , i.e.  $C_{23}H_{43}(OC_{23}H_{45}O)_3$ . *Triarachin*. Occurs in the kernels of *Nephtelium lappaceum*, and probably also in butter and in the oil from the ground nut (*Arachis hypogaea*) (Goldschmidt, J. 1877, 728; Sitz. W. [2] 74, 394; Oudemans, Z. 1867, 256; Gössmann, A. 89, 1). Sl. sol. ether.

*Mono-oleyl derivative*  $C_{27}H_{54}O_2$ , i.e.  $C_{23}H_{43}(OH)(OC_{23}H_{45}O)$ . *Mono-olein*. S.G. .91. Formed by heating oleic acid with excess of glycerin for 18 hours at 200° (Berthelot). Oil; may be solidified.

*Di-oleyl derivative*  $C_{54}H_{108}O_4$ , i.e.  $C_{23}H_{43}(OH)(OC_{23}H_{45}O)_2$ . S.G. .91. Oil.

*Tri-oleyl derivative*  $C_{81}H_{162}O_6$ , i.e.  $C_{23}H_{43}(OC_{23}H_{45}O)_3$ . *Tri-olein*. *Olein*. The chief constituent of fatty oils; occurs also in solid fats. May be formed by heating glycerin with excess of oleic acid at 240° (Berthelot). Oil. May be distilled *in vacuo*. Decomposed by distillation under atmospheric pressure, *n*-hexane and *n*-heptane being among the products (Engler, B. 22, 594). Slowly saponified by water and  $PbO$  at 100°. V. sl. sol. alcohol, v. e. sol. ether. Conc.  $H_2SO_4$  converts it into oily

oil (Geitel, J. pr. [2] 37, 85). Nitrous acid converts it into the isomeric solid elaidin, a crystalline substance, almost insol. alcohol, v. e. sol. ether, melting at [38°] (Duffy, C. J. 5, 197).

*Glycero-tartaric acid*  $C_8H_{14}O_6$ , i.e.  $C_2H_5(OH)_2.CO.CO.CH(OH).CH(OH).CO_2H$ . Formed by heating equivalent quantities of glycerin and tartaric acid to about 150° (Berzelius, *Handbuch*; Des Plats, C. R. 49, 216). Semi-solid mass; insol. ether, v. sol. alcohol, slowly resolved by water into glycerin and tartaric acid. —  $CaA_2$  3aq: deliquescent amorphous mass. —  $BaA_2$ .

*Glycero-di-tartaric acid*  $C_{10}H_{18}O_8$ , i.e.  $C_2H_5(OH)(O.CO.CH(OH).CH(OH).CO_2H)_2$ . From glycerin (1 pt.) and tartaric acid (1 pt.) by heating at 100° for 50 hours. An acid  $C_{11}H_{18}O_{12}$  is formed at the same time.

*Glycero-tri-tartaric acid*  $C_{12}H_{20}O_{10}$ . Formed by heating glycerin (1 pt.) with tartaric acid (20 pts.) at 140°. Tetrabasic acid.

*Mono-ethyl ether*  $C_8H_{16}O_4$ , i.e.  $C_2H_5(OH)(OEt)CH(OH).CH(OH).CH_2OEt$ . (225°–230°). Formed by heating chlorhydrin with  $NaOEt$  at 200°, treating the residue with water, then with  $K_2CO_3$ , agitating with ether, and fractionally distilling the extract (Reboul, A. Ch. [8] 9, 5). Liquid, sol. water, but separated therefrom by  $K_2CO_3$ .

*Di-ethyl ether*  $C_{10}H_{20}O_4$ , i.e.  $CH_3(OEt).CH_2(OH).CH_2(OEt)$ . (191°). S.G. .92. Formed by the action of  $NaOEt$  on dichlorhydrin (Reboul); or by heating glycerin with  $KOH$  and  $EtBr$  (Berthelot).

*Tri-ethyl derivative*  $C_{12}H_{24}O_6$ , i.e.  $C_2H_5(OEt)_3$ . *Triethylin*. (180°–190°). From the preceding by successive treatment with  $PCl_5$  and  $NaOEt$  (Reboul a. Lourenço, C. R. 52, 466). Oil.

*Isoamyl derivative*  $C_{11}H_{22}O_2$ , i.e.  $C_4H_9(OH)(OC_2H_5)$ . *Isoamylin*. (261°). S.G.

<sup>12</sup>-98. Formed by heating  $\text{CH}_2\text{CH}(\text{CH}_2\text{O.C}_2\text{H}_5)\text{CH}_2\text{O.C}_2\text{H}_5$

with water for some hours at 200° (Reboul). Oil.

*Di-isoamyl derivative*  $\text{C}_{15}\text{H}_{32}\text{O}_2$  i.e.  $\text{C}_5\text{H}_7(\text{OH})(\text{OC}_4\text{H}_9)_2$  (273°). S.G.  $\approx$  307. From dichlorhydrin and  $\text{NaOC}_4\text{H}_9$ .

*Ethyl-isoamyl derivative*  $\text{C}_{16}\text{H}_{34}\text{O}_2$  i.e.  $\text{C}_5\text{H}_7(\text{OH})(\text{OEt})(\text{OC}_4\text{H}_9)$  (239°). S.G.  $\approx$  92. From the mono-isoamylin by successive treatment with fuming HCl and  $\text{NaOEt}$ . Oil.

*Mono-allyl derivative*  $\text{C}_9\text{H}_{16}\text{O}_2$  i.e.  $\text{C}_3\text{H}_5(\text{OH})(\text{OC}_2\text{H}_5)$  (240°). S.G.  $\approx$  1.116. Occurs in the syrupy liquid left in the preparation of allyl alcohol by heating oxalic acid with excess of glycerin (Tollens, B. 5, 68; A. 156, 149). Liquid, m. sol. water. Br forms oily  $\text{C}_3\text{H}_5\text{Br}_2\text{O}_2$ .

*Tri-allyl derivative*  $\text{C}_{12}\text{H}_{20}\text{O}_3$  i.e.  $\text{C}_3\text{H}_5(\text{OC}_2\text{H}_5)_3$ . *Tri-allylin*. (232°). From glycerin, allyl iodide, and KOH (Berthelot, A. De Luca, A. 100, 361).

*Di-phenyl derivative*  $\text{C}_{15}\text{H}_{18}\text{O}_2$  i.e.  $\text{CH}_2(\text{OPh})\text{CH}(\text{OH})\text{CH}_2(\text{OPh})$ . [81°]. Formed by adding *s*-dichlorhydrin (70 g.) to phenol (100 g.) and KOH (60 g.) (Rössing, B. 19, 64). Pearly plates (from alcohol). Insol. water, m. sol. alcohol, v. e. sol. ether. When heated with  $\text{AcCl}$  (1 mol.) it gives  $\text{C}_{15}\text{H}_{18}\text{AcO}_2$  [71°], but with 4 pts.  $\text{AcCl}$  it forms liquid  $\text{C}_{15}\text{H}_{18}\text{O}_2$ . In like manner  $\text{BzCl}$  (1 mol.) forms  $\text{C}_{15}\text{H}_{18}\text{BzO}_2$  [67°] but boiling  $\text{BzCl}$  (7 pts.) forms oily  $\text{C}_{15}\text{H}_{18}\text{O}_2$ . Forms a stable sodium derivative  $\text{C}_{15}\text{H}_{18}\text{NaO}_2$ . On sulphonation it gives the disulphonic acid  $\text{CH}(\text{OH})(\text{CH}_2\text{O.C}_6\text{H}_4\text{SO}_3\text{H})_2$ , of which the salt  $\text{K}_2\text{A}^{2-}$  is v. sol. water.

*Di-nitro-phenyl derivative*  $\text{C}_{15}\text{H}_{14}\text{N}_2\text{O}_6$  i.e.  $\text{C}_6\text{H}_3(\text{OH})_2\text{OC}_6\text{H}_3(\text{NO}_2)_2$  [c. 83°]. From chloro-*m*-di-nitro-benzene, glycerin, and  $\text{KOH}\Delta\text{q}$  (Willgerodt, B. 12, 764).

*Benzylidene derivative*

$\text{C}_6\text{H}_5\text{CH}(\text{O})\text{C}_6\text{H}_4\text{OH}$ . From glycerin and benzoic aldehyde at 200° (Harnitzky a. Menschutkin, A. 136, 127). Oil. Decomposed by water.

*u-Chlorhydrin*  $\text{C}_3\text{H}_5\text{ClO}_2$  i.e.  $\text{CH}_2\text{Cl}(\text{CH}(\text{OH})\text{CH}_2\text{OH})$ .

*Chloro-propylene glycol*. Mol. w. 110.5. (218°) (Hanriot). S.G.  $\approx$  1.338. Formed, together with smaller quantities of the isomeric  $\text{CH}_2(\text{OH})\text{CHCl}(\text{CH}_2\text{OH})$ , by saturating glycerin with HCl and keeping the liquid for some hours at 100° (Berthelot, A. Ch. [8] 41, 296). Formed also by heating epichlorhydrin with water (Reboul; Hanriot, A. Ch. [5] 17, 62).

*Preparation*.—The product of the action of dry HCl on damp glycerin in sealed tubes at 100° is distilled under 18 mm. pressure, the *u*-chlorhydrin passing over at 139°, the *s*-isomeride at 146° (Hanriot). There is obtained about 16 times as much of the *u*- as of the *s*-chlorhydrin.

*Properties*.—Liquid, miscible with water, alcohol, and ether. Unless quite free from HCl it suffers condensation when distilled.

*Reactions*.—1. Sodium amalgam reduces it to propylene-glycol (Lourengo, C. R. 52, 1043; Buñ, Bl. [2] 10, 123).—2. Potassium cyanide forms a nitrile which is decomposed on distillation, but is converted by boiling with dilute

$\text{HNO}_3$  into di-oxy butyric acid (Hanriot, C. R. 86, 1139; Bl. [2] 27, 256).—3. Baryta acting on its ethereal solution forms small quantities of glycide and epichlorhydrin.—4. When heated with an aqueous solution of trimethylamine in sealed tubes it yields  $\text{C}_3\text{H}_7(\text{OH})\text{NMe}_3\text{Cl}$  and  $\text{C}_3\text{H}_7(\text{OH})\text{NMe}_3\text{HCl}$ . The former gives a crystalline platinumchloride  $(\text{C}_3\text{H}_7(\text{OH})\text{NMe}_3\text{Cl})_2\text{PtCl}_4$  and aurochloride  $\text{C}_3\text{H}_7(\text{OH})\text{NMe}_3\text{AuCl}$  (Hanriot; V. Meyer, Z. [2] 5, 439).

*Di-nitrate*  $\text{CH}_2\text{Cl}(\text{CH}(\text{O.NO}_2)\text{CH}_2(\text{O.NO}_2))$ . S.G.  $\approx$  1.511. From chlorhydrin,  $\text{H}_2\text{SO}_4$ , and  $\text{HNO}_3$  (Henry, A. 155, 164).

*Di-formyl derivative*  
 $\text{CH}_2\text{Cl}(\text{CH}(\text{OCHO})\text{CH}_2(\text{OCHO}))$ . (185°–195°) at 22 mm. Formed from the chlorhydrin by heating with nitro-methane at 180° (Pfungst, J. pr. [2] 34, 36).

*Acetyl derivative*  $\text{C}_5\text{H}_8(\text{OH})(\text{OAc})\text{CH}_2\text{Cl}$ . (250°). *Aceto-chlorhydrin*. Formed, together with dichlorhydrin, by passing HCl into a mixture of acetic acid and glycerin at 100°; also, together with the following, by the action of  $\text{AcCl}$  on glycerin (Berthelot, A. De Luca, A. Ch. [3] 52, 433). From epichlorhydrin and  $\text{HOAc}$  at 100° (Reboul, A. Suppl. 1, 232).

*Di-acetyl derivative*  
 $\text{CH}_2(\text{OAc})\text{CH}(\text{OAc})\text{CH}_2\text{Cl}$ . (245°). S.G.  $\approx$  1.243. From acetyl chloride and a mixture of equal volumes of glycerin and  $\text{HOAc}$  (Berthelot, A. De Luca, A. Ch. [3] 52, 401; cf. Franchimont, R. T. C. 1, 43). Also from epichlorhydrin and  $\text{Ac}_2\text{O}$  at 180°, a compound  $\text{C}_{11}\text{H}_{17}\text{ClO}_4$  (240° at 20 mm.) being formed at the same time (Truchot, A. 138, 239).

*Di-palmityl derivative*  
 $\text{C}_{15}\text{H}_{31}\text{Cl}(\text{OC}_{15}\text{H}_{31}\text{O})_2$ . [44°]. From glycerin and palmityl chloride (Villier, B. 9, 1933).

*Stearyl derivative*  
 $\text{C}_{15}\text{H}_{31}\text{Cl}(\text{OH})(\text{OC}_{17}\text{H}_{33}\text{O})$ . [28°]. Produced by passing HCl into a mixture of stearic acid and glycerin (Berthelot).

*Benzoyl derivative*  $\text{C}_5\text{H}_8\text{Cl}(\text{OH})(\text{OBz})$ . [–40°]. From glycerin,  $\text{IOBz}$ , and HCl (Berthelot, A. Ch. [3] 41, 302).

*Ethyl derivative*  
 $\text{CH}_2\text{Cl}(\text{C}_2\text{H}_5(\text{OH})(\text{OEt}))$  (188°). From epichlorhydrin and  $\text{HOEt}$  at 180°. Formed also from  $\text{CH}_2\text{CH}(\text{CH}_2\text{OEt})\text{CH}_2\text{OEt}$  and HCl (Reboul, A. Suppl. 1, 236).

*Isoamyl derivative*  
 $\text{CH}_2\text{Cl}(\text{C}_5\text{H}_7(\text{OH})(\text{OC}_4\text{H}_9))$ . (265°). S.G.  $\approx$  1.0. Formed from epichlorhydrin and isoamyl alcohol at 220° (Reboul).

*s-Chlorhydrin*  $\text{CH}_2(\text{OH})\text{CHCl}(\text{CH}_2\text{OH})$ . *Chloro-trimethylene glycol*. (145° at 10 mm.). S.G.  $\approx$  1.328. Occurs in small quantity among the products of the action of HCl on glycerin at 100°, and may be isolated by fractional distillation *in vacuo* (Hanriot, C. R. 86, 1139; A. Ch. [5] 17, 73). Formed also by the action of  $\text{HOCl}$  on allyl alcohol (Henry, A. 155, 822). Liquid, resembling the *u*-isomeride. It has a great tendency to form polyglyceric derivatives.

*Acetyl derivative*  
 $\text{CH}_2(\text{OH})\text{CHCl}(\text{CH}_2(\text{OAc}))$ . (230°). S.G.  $\approx$  1.27. From allyl acetate and  $\text{HOCl}$ .

*Ethyl derivative*  
 $\text{CH}_2(\text{OH})\text{CHCl}(\text{CH}_2(\text{OEt}))$ . (183°). S.G.  $\approx$  1.1

1-117. From ethyl allyl oxide and  $\text{HOCl}$  (Lauch, B. 18, 2287). Thick liquid.

*Di-ethyl derivative*

$\text{CH}_3(\text{OEt})\text{CHClCH}_2(\text{OEt})$ . (184°). S.G. 1.1005. From di-ethyl-glycerin and  $\text{PCl}_5$  (Reboul a. Lourenço, A. 119, 287).

*Dichlorhydrins v. Di-chloro-propyl alcohols.*

*Chloro-bromhydrins*  $\text{CH}_2\text{Br.C}_2\text{H}_4\text{Cl}(\text{OH})$ . (198°). S.G. 1.1740. From allyl bromide and  $\text{HOCl}$  (obtained from chloride of lime and boric acid) (Lauch, B. 18, 2288). Also from epichlorhydrin and  $\text{HBr}$  and from epibromhydrin and  $\text{HCl}$  (Reboul, A. Suppl. 1, 225). Liquid. Conc.  $\text{KOH}$  aq. gives epichlorhydrin.

*Acetyl derivative*  $\text{C}_4\text{H}_7\text{BrCl}(\text{OAc})$ . (228°). From glycerin,  $\text{AcCl}$ , and  $\text{AcBr}$  (Berthelot a. De Luca, A. Ch. [3] 52, 462). Sl. sol. water.

*Ethyl derivative*  $\text{C}_4\text{H}_7\text{BrCl}(\text{OEt})$ . (187°). From epichlorhydrin and  $\text{EtBr}$  (Reboul a. Lourenço, A. 119, 238).

*Bromhydrin*  $\text{C}_2\text{H}_4\text{Br}_2$ , i.e.

$\text{CH}_2(\text{OH})\text{CHBr.CH}_2(\text{OH})$ ? (180° at 10 mm.). Formed by adding glycerin (500 g.) in small portions to liquid bromide of phosphorus (550 g.), the liquid being kept cool and the product after 24 hours fractionally distilled *in vacuo* (Berthelot a. De Luca, A. Ch. [3] 48, 304; 52, 433). Oil, sol. ether. In its preparation there is also formed  $\text{C}_2\text{H}_4\text{Br}_2\text{O}$  (below 200°) and crystalline  $\text{C}_2\text{H}_4\text{Br}_2\text{P}$  which is not affected by aqueous  $\text{KOH}$  at 100°.

*Acetyl derivative*  $\text{C}_4\text{H}_7\text{Br}(\text{OH})(\text{OAc})$ . (170°-180°) at 10 mm. Prepared by the action of  $\text{AcBr}$  (1.5 pts.) on dry glycerin (1.2 pts.) the crude product being distilled under 10 mm. pressure; the yield is good (2-2 pts.) (Hanriot, A. Ch. [5] 17, 84). Reduced by the copper-zinc couple to tri-methylene glycol.

*Di-ethyl derivative*  $\text{C}_4\text{H}_7\text{Br}(\text{OEt})_2$ . (195°-205°). S.G. 1.258. From di-ethyl-glycerin and  $\text{PBr}_3$  (Henry, B. 4, 704).

*Bromhydrin*  $\text{C}_2\text{H}_4\text{Br}_2$ , i.e.

$\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{Br}$ . (138° at 17 mm.). A product of the action of  $\text{Br}$  on allyl alcohol in presence of water (Fink, M. 8, 561). By the action of  $\text{HBr}$  on dry glycerin, Veley (C. N. 47, 39) obtained a bromhydrin (160°) at 60 mm.; S.G. 1.717.

*Di-bromhydrins v. Di-bromo-propyl alcohols.*

*Tri-bromhydrin v. Tri-bromo-propane.*

*Iodhydrin*  $\text{C}_2\text{H}_4(\text{OH})_2\text{I}$ . S.G. 1.203. From chlorhydrin and  $\text{KI}$  (Reboul, A. Ch. [3] 60, 5).

*Di-iodhydrin v. Di-iodo-propyl alcohol.*

*Chloro-iodhydrin v. Chloro-iodo-propyl alcohols.*

*Methyl derivative*  $\text{C}_3\text{H}_7\text{Cl}(\text{OMe})$ . (c. 200°). Formed by heating epichlorhydrin (? mol.) with  $\text{MeI}$  (1 mol.) at 190°; the yield being 20 p.c. of the theoretical (Baal, B. 21, 2971). Oil, volatile with steam.

*Ethyl derivative*  $\text{C}_3\text{H}_7\text{Cl}(\text{OEt})$ . (200°-210°).

*Isopropyl derivative*  $\text{C}_3\text{H}_7\text{Cl}(\text{OPr})$ . (208°-212°).

*n-Propyl derivative*  $\text{C}_3\text{H}_7\text{Cl}(\text{OPr})$ . (200°-210°).

*Diglycerin*  $\text{C}_4\text{H}_9\text{O}_2$ , i.e.

$\text{C}_2\text{H}_5(\text{OH})_2\text{O.C}_2\text{H}_5(\text{OH})_2$ , *Pyroglycerin*. (220°-

230°) at 10 mm. When glycerin, diluted with one-third of its bulk of water, is saturated at 100° with  $\text{HCl}$ , then mixed with an equal bulk of glycerin, and heated with inverted condenser for 13 hours at 120°, there is obtained a mixture of dichlorhydrin, diglycerin chlorhydrin, diglycerin dichlorhydrin, diglycerin, and triglycerin; these may be separated by fractional distillation *in vacuo* (Lourenço, C. R. 52, 559). Thick liquid, insol. ether, sl. sol. cold, v. sol. hot water, miscible with alcohol.

*Mono-stearyl derivative*

$\text{C}_2\text{H}_5(\text{O.C}_2\text{H}_5\text{O})(\text{OH})\text{O.C}_2\text{H}_5(\text{OH})_2$  [about 30°]. Formed by heating glycerin alone for some time and then with stearic acid for several days at 240°. Crystallised from alcohol (Hundeshagen, J. pr. [2] 23, 252). Wax-like solid, sol. ether. Readily saponified by alcoholic potash.

*Tri-ethyl derivative*  $\text{C}_6\text{H}_{13}\text{O}_3$ , i.e.

$\text{C}_2\text{H}_5(\text{OH})(\text{OEt})\text{O.C}_2\text{H}_5(\text{OEt})_2$ . (c. 290°). S.G. 1.190. Formed, together with di-ethyl-glycerin and tetra-ethyl-triglycerin, by the action of  $\text{NaOEt}$  on epichlorhydrin (Reboul a. Lourenço, C. R. 52, 401). Liquid, sol. water, alcohol, and ether. Ppd. from its aqueous solution by  $\text{K}_2\text{CO}_3$ .

*Diglycerin chlorhydrin*  $\text{C}_4\text{H}_7\text{ClO}_2$ . (270°). Formed together with diglycerin dichlorhydrin  $\text{C}_4\text{H}_7\text{Cl}_2\text{O}_2$  by heating glycerin saturated with  $\text{HCl}$ . By heating either chlorhydrin with alcoholic  $\text{KOH}$  at 100° there is formed pyroglycide  $\text{C}_4\text{H}_7\text{O}_2$  (245°-255°). This body is also got by heating polymerised glycide acetate with  $\text{NaOH}$  (Breslau, J. pr. [2] 20, 193). It is miscible with water and alcohol.

*Di-ethyl derivative of diglycerin chlorhydrin*  $\text{C}_6\text{H}_{13}\text{ClO}_2$ , i.e.  $\text{OC}_2\text{H}_5(\text{OH})(\text{OEt})\text{Cl}$ . (285°). S.G. 1.11. Formed by heating di-ethyl-glycerin with epichlorhydrin at 200°. Formed also, together with ethyl- and di-ethyl-chlorhydrin, by heating epichlorhydrin with alcohol at 200°. Liquid, sl. sol. water, miscible with alcohol and ether.

*Acetyl derivative of diglycerin tri-chlorhydrin*  $\text{C}_6\text{H}_{13}\text{Cl}_3\text{O}_3$ , i.e.  $\text{OC}_2\text{H}_5(\text{OAc})\text{Cl}_2$ . (190°) at 20 mm. A product of the action of  $\text{AcCl}$  on epichlorhydrin (Truchot, A. 140, 245).

*Triglycerin*  $\text{C}_6\text{H}_{13}\text{O}_3$ , i.e.

$\text{C}_2\text{H}_5(\text{OH})_2\text{O.C}_2\text{H}_5(\text{OH})(\text{OEt})\text{O.C}_2\text{H}_5(\text{OH})_2$ . (275°-285°) at 10 mm. Formed as described under diglycerin. Thick liquid.

*Tetra-ethyl derivative of triglycerin*  $\text{C}_{11}\text{H}_{23}\text{O}_4$ , i.e.  $\text{C}_2\text{H}_5\text{O}_2(\text{OH})(\text{OEt})_2$ . (200°) at 10 mm. S.G. 1.022. A product of the action of  $\text{NaOEt}$  on epichlorhydrin. Liquid, sol. water, alcohol and ether.

*Acetyl derivative of triglycerin tetra-chlorhydrin*  $\text{C}_{11}\text{H}_{23}\text{Cl}_4\text{O}_4$ , i.e.  $\text{C}_2\text{H}_5\text{O}_2(\text{OAc})\text{Cl}_2$ . (260°) at 20 mm. From epichlorhydrin and  $\text{AcCl}$  at 100° (Truchot, A. 140, 245).

*Hexaglycerin bromhydrin*

$\text{C}_6\text{H}_{13}\text{BrO}_2$ . One of the products of the action of  $\text{PBr}_3$  on glycerin. Crystalline. Sl. sol. boiling ether.

*Thioglycerin*  $\text{C}_3\text{H}_7\text{O}_2\text{S}$  i.e.  $\text{C}_2\text{H}_5(\text{OH})_2(\text{SH})$ . Mol. w. 108. S.G. 1.295. From chlorhydrin and boiling alcoholic  $\text{KSH}$ ; the product is acidified and evaporated below 50° (Carius, A. 122, 72; 124, 222). Thick liquid; v. sl. sol.

water, insol. ether, miscible with alcohol. Reacts like mercaptan with metallic oxides and salts. Decomposed by heat into water  $H_2S$  and thiopyroglycide  $C_4H_4O_3S$  an amorphous body, insol. water and ether, sl. sol. boiling alcohol. Nitric acid oxidises thioglycerin to  $C_4H_4(OH)SO_3H$ . —  $Hg(C_2H_4O_2S)_2$ : [50°–60°]; white powder. —  $Pb(C_2H_4O_2S)_2$ : [c. 80°]; yellow pp.

**Di-thio-glycerin**  $C_4H_8OS_2$ , *i.e.*

$C_4H_8(OH)(SH)_2$ . Mol. w. 124. S.G. <sup>14</sup> 1.342. From *s*-dichlorhydrin and alcoholic KHS (Carius). Thick liquid, insol. ether, v. sl. sol. water, v. e. sol. alcohol. Split up on distillation into water,  $H_2S$ , and trithiopyroglycide  $C_4H_4OS_3$ .  $HNO_3$  forms an acid  $C_4H_4S_3O_6$ . —  $HgC_2H_4OS_2$ : [c. 90°]. —  $PbC_2H_4OS_2$ : yellow powder.

Trithioglycerin  $C_4H_8S_3$ , *i.e.*  $C_4H_8(SH)_3$ . Mol. w. 140. S.G. <sup>14</sup> 1.391. From *s*-trichloro-propane and alcoholic KSH (Carius). Liquid, m. sol. alcohol, insol. ether and water. Split up by heat into  $H_2S$  and dithioglycerin  $C_4H_8S_2$ . —  $Cu_2(C_2H_4S_2)_3$ . —  $Pb_2(C_2H_4S_2)_3$ . —  $Ag_3C_2H_4S_2$ .

**GLYCEROL** *v.* **GLYCERIN**.

**GLYCEROSE** *v.* **GLYCERIN**, *Reaction 6*.

**GLYCERYL**. The trivalent radicle  $C_3H_5$ .

**GLYCERYL BORATE**  $C_3H_5BO_3$ . Formed by heating glycerin with  $B_2O_3$  (Schiff a. Beehi, Z. 1866, 147). Glassy mass resolved by hot water into glycerin and boric acid. Not affected by boiling alcohol.

**GLYCERYL CARBAMATE**  $C_4H_9(O.CO.NH_2)_3$ . [215°]. From chloroformamide and glycerin (Gattermann, A. 244, 42). Needles (from HOAc). Insol. most solvents.

**GLYCERYL CHLORIDE** *v.* **TRI-CHLORO-PROPANE**.

**GLYCERYL TRI-PHENYL-TRI-CARBAMATE**  $C_{21}H_{27}N_3O_6$ . Phenyl-carbamio-glyceride. Formed by heating glycerin (1 mol.) with phenyl cyanate (3 mols.) (Tessmer, B. 18, 963). White powder or fine needles. Sol. alcohol, acetone, ether, and chloroform, sl. sol. water and benzene. By heating with  $Ba(OH)_2$  and water to 150° it yields glycerin, aniline, and  $BaCO_3$ .

**GLYCERYL SULPHOCYANIDE**  $C_4H_7N_3S$ , *i.e.*  $C_3H_5(SCy)_3$ . [126°]. S. (alcohol) .25 at 13°. From *s*-tri-bromo-propane and alcoholic KSCy at 100° (Henry, B. 2, 637). Small brittle needles (from alcohol). Insol. water, v. sol. boiling alcohol. Gives off HCl when heated.

**GLYCIDAMINE**  $C_4H_7NO$  *i.e.*

$CH_2.CH.CH_2NH_2$ . *Glyceramine*. Formed, together with

ther with 'diamidohydrin'  $C_4H_7N_2O$  by the action of alcoholic  $NH_3$  on *s*-dichlorhydrin (Claus, A. 168, 29). —  $BHCl$ : crystals, ppd. by adding ether to the alcoholic solution; very hygroscopic. —  $B'H.PtCl_4$ : transparent needles.

**GLYCIDIC ACID** *v.* **GLUCIC ACID**.

**GLYCIDIC ACID**  $C_3H_4O_3$ , *i.e.*  $O < \begin{smallmatrix} CH_2 \\ CH.CO.H \end{smallmatrix}$ . (160°) (B.); (157°) (H.). S.G. <sup>22</sup> 1.165. Prepared by adding powdered caustic soda (but not potash) to an ethereal solution of its acetate (Breslau, J. pr. [2] 20, 192; cf. Gegerfelt, Bl. [2] 23, 160). Obtained by the action of  $BaO$  (28 g.) upon chlorhydrin (48 g.), dissolved in ether (50 g.) (Hanriot, Vol. II.

C. R. 88, 387). Mobile liquid, miscible with water, alcohol, and ether. Heated with water it forms glycerin. Reduces ammoniacal silver nitrate in the cold. In presence of glycerin it rapidly forms products of condensation. Dilute  $HNO_3$  forms glycerin mononitrate. Distillation with  $KHSO_4$  gives acrolein.

**Acetyl derivative**

$O < \begin{smallmatrix} CH_2 \\ CH.CH_3.OAc \end{smallmatrix}$  (166°) (B.); (169°) (G.). S.G. <sup>22</sup> 1.129. Obtained by heating dry powdered potassic acetate with an equivalent quantity of epichlorhydrin over an oil bath, the temperature of which is slowly raised from 110° to 150°. After 20 hours the mass is extracted with ether and fractionated. An isomeric liquid (260°). S.G. <sup>22</sup> 1.204 is got as a by-product (Breslau). Reduces ammoniacal  $AgNO_3$ .

**Ethyl derivative**  $O < \begin{smallmatrix} CH_2 \\ CH.CH_3.OEt \end{smallmatrix}$

(129°). S.G. <sup>12</sup> .94. Formed by the action of KOH on the ethyl-chlorhydrin derived from ethyl allyl oxide and KOH (Reboul, A. Ch. [3] 60, 5; Henry, B. 5, 449). Liquid, sol. water. Readily combines with HCl.  $PCl_5$  gives  $C_2H_5Cl(OEt)$ .

**Isoamyl derivative**  $C_7H_{13}O_3$ , *i.e.*  $O < \begin{smallmatrix} CH_2 \\ CH.CH_2.C_4H_9 \end{smallmatrix}$  (188°). S.G. <sup>12</sup> .90. From isoamyl-chlorhydrin and KOH.

**Pyruvyl derivative**  $C_5H_7O_3$ , *i.e.*

$O < \begin{smallmatrix} CH_2 \\ CH.CH_3.CO.CO.CH_3 \end{smallmatrix}$  (?) [82°] (E.); [78°] (J.). (260°). Formed by heating equi-molecular proportions of glycerin and glyceric acid at 120°, and crystallising the product from alcohol (Erhart, M. 6, 511). Formed also by distilling glycerin with tartaric acid (Jowanowitsch, M. 6, 467). Needles, sol. hot water, but slowly saponified thereby, sol. alcohol, benzene, and ether. Monoclinic:  $a:b:c = 1.48:1.77$ ;  $\beta = 105^\circ 33'$ . Readily saponified by alkalis, alkaline earths, and their carbonates. Bromine forms di-bromopyruvic acid. Sodium-amalgam gives lactic acid. It forms the following salts which are derived from its hydrate  $C_5H_7O_6$ . —  $KC_5H_7O_6$ : silky needles. —  $Ca(C_5H_7O_6)_2$ : 2aq. —  $Cu(C_5H_7O_6)_2$ : 8aq; blue crusts. —  $AgC_5H_7O_6$ : needles.

**GLYCIDIC ACID**  $C_3H_4O_3$ , *i.e.*

$O < \begin{smallmatrix} CH_2 \\ CH.CO.H \end{smallmatrix}$ . *Oxy-acrylic acid*.

**Formation**.—1. By the action of alcoholic KOH on the  $\alpha$ -chloro- $\beta$ -oxy-propionic acid that is formed by the union of acrylic acid with HOCl (Melikoff, B. 13, 271; 14, 939).—2. In like manner from the isomeric  $\beta$ -chloro- $\alpha$ -oxy-propionic acid (Erlenmeyer, B. 13, 458).

**Properties**.—Liquid, miscible with water, alcohol, and ether. Slowly combines with water, becoming glyceric acid. Its calcium salt readily takes up water, changing to calcium glycerate. Conc.  $HCl$  forms  $\beta$ -chloro- $\alpha$ -oxy-propionic acid.

**Salts**.— $NH_4A'$ . —  $KA'$  ½aq: small prisms. —  $NaA'$  ½aq. —  $ZnA'$  aq: amorphous. —  $AgA'$ : trimetric tables; when its aqueous solution is boiled it deposits a silver mirror.

**Ethyl ether EtA'**. (162° uncor.). S.G. <sup>22</sup> 1.0933. From silver  $\beta$ -chloro- $\alpha$ -oxy-propionate and EtI (Melikoff, B. 21, 2058). Oil; smelling somewhat like malonic ether.

Homologues of glycidic acid v. METHYL-GLYCIDIC ACID.

GLYCINE v. GLYCOCOLL.

GLYCO-DI-AMIDO-BENZOIC ACID

$C_{12}H_{10}N_2O_5$ , *i.e.*  $CO_2H.C_6H_3(NH_2).CO_2H.O_2$ . Formed by heating a conc. aqueous solution of glucose (2 mols.) and diamido-benzoic acid (1 mol.) for some hours at  $90^\circ$  (Griess a. Harrow, *B.* 30, 2210). Small silvery plates (from water); v. sl. sol. cold water, nearly insol. alcohol and ether. Decomposed by melting. Not affected by boiling with aqueous HCl or baryta. Strongly dextrorotatory.— $BaA'$  (at  $100^\circ$ ): amorphous.— $HA'HCl$ : small plates; v. e. sol. water and alcohol.

**GLYCOCHOLIC ACID**  $C_{26}H_{42}NO_8$ . S.  $\cdot 33$  in the cold;  $\cdot 83$  at  $100^\circ$  (Strecker);  $\cdot 033$  at  $20^\circ$ ;  $\cdot 85$  at  $100^\circ$  (Emich). S. (ether)  $\cdot 093$  at  $20^\circ$ ; S. (benzene)  $\cdot 009$ ; S. (CHCl<sub>3</sub>)  $\cdot 011$ .  $[\alpha]_D = 29.9^\circ$  (Hoppe, *C. C.* 1859, 65). Occurs as sodium salt in the bile of animals, and in ox-bile it is accompanied by sodium taurocholate, cholesterol, pigments, &c. (Gmelin; Strecker, *A.* 65, 9; 67, 1; 70, 161, 166; Emich, *M.* 3, 326; *M.* 4, 108; Gorup-Besanez, *A.* 157, 286).

**Preparation.**—1. The pp. formed in fresh ox-bile by  $Pb(OAc)_2$  is treated with boiling (85 p.c.) alcohol, and the hot filtrate decomposed by  $H_2S$ , mixed with water and set aside to crystallise.—2. Fresh ox-bile is evaporated to dryness over the water-bath; the residue is extracted with cold alcohol, and the filtrate mixed with a little ether. After some time the liquid is decanted from the sticky deposit, and more ether is added when the mixed sodium salts (Plattner's 'crystallised bile') slowly deposit. They are dissolved in water and dilute  $H_2SO_4$  added, whereupon glycocholic acid slowly crystallises.—3. The readiest way of obtaining glycocholic acid consists in covering fresh bile in a tall cylinder with a layer of ether, and adding 2 c.c. of conc. HClAq for every 50 c.c. of the bile. The whole then usually solidifies after a while to a crystalline pulp of glycocholic acid, which may be re-crystallised from water (Hüfner, *J. pr.* [2] 10, 267). In this experiment the bile of castrated oxen and of calves does not crystallise; of other oxen it always crystallises; the bile of cows usually crystallises (Hüfner, *J. pr.* [2] 19, 302). Bile which when mixed with ether and HCl produces a crystalline pp. of glycocholic acid, contains in 100 pts. of mixed taurocholic and glycocholic acids from 71 to 88 pts. of the latter acid, while bile which does not produce such crystallisation contains only from 47 to 57 pts. of glycocholic acid to 53 and 43 pts. of taurocholic acid respectively (G. Hüfner, *J. pr.* [2] 25, 97). Nevertheless it cannot be held that taurocholic acid hinders the crystallisation of glycocholic acid, because a solution containing even 7 pts. of pure sodic taurocholate to 1 pt. of pure sodic glycocholate gives crystallisation when treated with HCl and ether. The cause of non-crystallisation is therefore not yet explained (H.).—4. According to Marshall (*H.* 11, 233), the quickest method of obtaining glycocholic acid in colourless crystals is as follows:—A drop of hydrochloric acid is added to fresh bile; the mixture shaken and filtered; ethyl ether and hydrochloric acid are then added to the filtrate; the mixture shaken and allowed to remain. The crystals formed are

collected on a filter, washed with water holding hydrochloric acid and ether in solution, and dried in the air. By re-crystallisation they are obtained perfectly colourless.

**Properties.**—Bulky groups of slender needles. V. sl. sol. water, v. e. sol. alcohol, v. sl. sol. other solvents. Its aqueous solution has a sweet and slightly bitter taste. It reddens litmus. It is readily soluble in ammonia, aqueous alkalis, and baryta-water; the addition of acids to these solutions repts. the acids in a resinous form which slowly becomes crystalline; this change is rapidly brought about by ether. The free acid and its salts are dextrorotatory. It is antiseptic. By heating above  $140^\circ$  it is converted into glycocholononic acid  $C_{26}H_{42}NO_8$ . With sugar and conc.  $H_2SO_4$  it gives on warming the crimson colour characteristic of Pettenkofer's test (v. BILZ). Solutions of glycocholic acid are not pptd. by gelatin (Maly a. Emich, *M.* 6, 95).

**Reactions.**—1. Boiling aqueous KOH sp. it up into glycocoll and cholic acid  $C_{24}H_{40}O_5$ . Boiling baryta-water effects the like hydrolysis.—2. Conc. HClAq and conc.  $H_2SO_4$  dissolve it in the cold, and water repts. it from these solutions, but the boiling acids deposit oily drops of glycocholononic acid which solidify after a while.—3. Boiling dilute HCl forms cholidic acid, dyslysin, and glycocoll.—4. Nitrous acid vapour passed into its solution forms 'ehologlycolic acid'  $C_{26}H_{42}O_8$  (Lang, *B.* [2] 25, 180). This acid is amorphous, but forms a crystalline barium salt  $Ba(C_{26}H_{40}O_8)_2$ , 3aq.—5. When mixed with HOAc and  $H_2SO_4$  and heated it forms an orange colouring matter possibly related to the bile-pigments (Michailoff, *B.* 17, 444, *Ref.*; *J. R.* 1884 [1] 584).—6. By heating with alcoholic  $NH_3$  at  $170^\circ$  for 24 hours there is formed a substance  $C_{26}H_{42}NO_8$ , which on evaporation crystallises in long silky deliquescent needles [ $125^\circ$ ] (Pellizzari, *C. C.* 1888, 1350).

**Salts.**—Solutions of the alkaline salts lather like soap. All the glycocholates are soluble in alcohol, those of the alkalis and alkaline earths dissolve easily in water, the rest are sparingly soluble and may be obtained by precipitation.— $NaA'$  (at  $100^\circ$ ). S. (alcohol) 1.5. The alcoholic solution deposits crystals when very slowly evaporated in a flask. Dry ether added to its alcoholic solution throws it down in an amorphous state, but if the ether is wet it becomes crystalline (Städeler, *J. pr.* 72, 257).— $BaA'$  (at  $100^\circ$ ) amorphous, S. 16.2 at  $15^\circ$ .— $PbA'_2$  (at  $100^\circ$ ).

**Ethyl ether**  $C_{26}H_{42}EtNO_8$ . S.G.  $\cdot 901$ . Prepared by saturating an alcoholic solution of the acid with HCl and heating in sealed tubes (Springer, *Am.* 1, 181). Slowly saponified by water.

**Paraglycocholic acid**  $C_{26}H_{42}NO_8$  [ $184^\circ$ ]. When glycocholic acid is pptd. by  $H_2SO_4$  from a solution of its Na salt, and the pp. is boiled with water paraglycocholic acid remains undissolved. Alcohol and boiling alkalis reconvert it into the ordinary modification.

**GLYCOCOLL**  $C_2H_3NO_2$ , *i.e.*  $CH_2(NH_2).CO_2H$  or  $CH_2 \begin{smallmatrix} CO.O.NH \\ NH_2.O.CO \end{smallmatrix} CH_2$  or  $CH_2 \begin{smallmatrix} CO \\ NH_2 \end{smallmatrix} O$ .

**Amido-acetic acid.** Mol. w. 75. ( $232^\circ$ – $236^\circ$  cor.). S. 23. S.G. 1.161. H. C. 228,000 (Stohmann,

*J. pr.* [2] 81, 285). Occurs in the mussel *Pecten irradians* (Ohlthenden, *A.* 178, 278).

**Formation.**—1. Discovered by Braconnot (*A. Ch.* [2] 13, 114), who obtained it by boiling gelatin with dilute  $H_2SO_4$ .—2. Formed also by boiling gelatin with potash or baryta (Mulder, *J. pr.* 16, 290).—3. By boiling hippuric acid with dilute HCl (Dessaignes, *A.* [3] 17, 50; Kraut & Hartmann, *A.* 133, 99).—4. By decomposing glycocholic or hyglycocholic acid with dilute acids or alkalis (Strecker, *A.* 67, 25; 70, 188).—5. From bromo-acetic acid and  $NH_3$  (Perkin & Duppa, *A.* 108, 112).—6. Together with  $CO_2$  and  $NH_3$  by heating uric acid with conc. HIAq at  $165^\circ$  (Strecker, *Z.* [2] 4, 215).—7. By the action of aqueous HI on hydantoic acid (Menschutkin, *A.* 153, 105).—8. From nitroso-thio-hydantoin or nitroso-thio-glycollic acid and HI (Andreasch, *M.* 6, 827).—9. From glyoxal by successive treatment with ammonium cyanide and dilute  $H_2SO_4$  (Lubavine, *Bl.* [2] 38, 379).—10. By passing cyanogen into boiling HIAq (S.G. 1:96) (Emmerling, *B.* 6, 1351).—11. From cyanoformic ether, zinc, and HCl (Wallach, *A.* 184, 13).—12. To the extent of about 7.5 p.c. by boiling silk with dilute  $H_2SO_4$  (Weyl, *B.* 21, 1531).

**Preparation.**—1. Hippuric acid 500 g. is boiled with conc. HCl for 12 hours. The benzoic acid formed is removed by filtration and extraction with ether, after which the liquor containing the hydrochloride of glycocoil is evaporated until crystallisation sets in. The salt is washed with absolute alcohol. The yield is 90 p.c. (Curtius & Goebel, *J. pr.* [2] 37, 157).—2. Hippuric acid (1,200 g.) is boiled for 12 hours with  $H_2SO_4$  (1,600 g.), diluted with water (3,200 g.). The product is allowed 24 hours to cool, it is then filtered. The filtrate is evaporated and shaken three times with ether to remove the last traces of benzoic acid. The liquid is diluted and neutralised with baryta (free from iron). The liquid is decanted from  $BaSO_4$  and evaporated. Some of the dissolved barium can be removed by  $CO_2$ . The glycocoil crystallises out from the evaporated filtrate (T. Curtius, *J. pr.* [2] 26, 153).—3. By heating chloro-acetic acid (1 pt.) with solid ammonium carbonate (3 pts.) to  $70^\circ$  and finally to  $130^\circ$  (Nencki).—4. Chloro-acetic acid (50 g.) and sodium carbonate (23 g.) are warmed with excess of aqueous ammonia. After boiling for 7 hours hydrochloric acid is added and the liquid evaporated, ppd. with alcohol and filtered. The filtrate is digested with  $Cu(HO)_2$ , warmed, filtered, and treated with alcohol, and then with hydrogen sulphide (Mauthner & Suida, *M.* 9, 728).—5. By heating phthaloxyl-amido-acetic acid  $CO_2H.C_6H_4.CO.NH.CH_2.CO_2H$  with double its weight of 20 p.c. pure HCl, diluting with water, filtering, evaporating, and treating with ice-cold water, which leaves behind phthalic acid. On evaporating and washing with absolute alcohol, hydrochloride of glycocoil remains as a snow-white crystalline powder (S. Gabriel & K. Kroschberg, *B.* 22, 428).

**Properties.**—Monoclinic tablets;  $a:b:c = 1:1.857:2.204$ ;  $\beta = 68^\circ 20'$  (Sohabus). Slight impurities change the crystalline form remarkably: traces of NaOH or TiOH cause it to form rhombohedra, while traces of baryta induce the formation of very long thin prisms (Curtius). Glycocoil is inactive. It has a sweet taste. Sol.

sol. water, insol. ether and alcohol. Neutral to litmus. It prevents the ppn. of cupric hydroxide from its sulphate by potash (Horsford, *A.* 60, 1).  $FeCl_3$  gives a deep-red colour (Engel, *Fr.* 16, 344).

**Reactions.**—1. Distillation with BaO gives methylamine and  $BaCO_3$ . Solid KOH acts in like manner but  $NH_3$ , hydrogen, and potassium oxalate are also formed (Cahours, *A. Ch.* [3] 53, 322; *A.* 109, 29).—2. Dilute  $H_2SO_4$  and  $MnO_2$  give off  $CO_2$  and HCN.—3. Nitrous acid gas converts it into glycollic acid (Socoloff & Strecker, *A.* 80, 18; Dessaignes, *J. Ph.* [3] 32, 44). Hippuric acid is also formed by treating zinc or silver glycocoil with  $BzCl$  (Dessaignes, *C. R.* 87, 251).—5. Cyanamide forms glycoeyamine  $C_6H_5N_3O_2$  (Strecker, *C. R.* 52, 1212).—6. Phenylcyanamide in ammoniacal solution mixed with an alcoholic solution of glycocoil forms on standing crystalline grains of  $C_6H_5N_3O_2$  (Berger, *B.* 13, 992).—7. With sodium hypobromite nitrogen is evolved (Denigès, *C. R.* 107, 662).—8. When a concentrated solution of glycocoil is mixed with NaOH and phenyl-acetic chloride a reaction takes place and on acidifying phenyl-aceturic acid separates. Its ether  $C_6H_5N_3O_2Et$  crystallises in broad prisms [79].—9. When benzoic aldehyde is added to an aqueous solution of glycocoil saturated with  $SO_2$ , there is formed syrupy  $C_6H_5NSO_2$ , which slowly solidifies over  $H_2SO_4$  (Schiff, *A.* 210, 125). *Chenanthol* forms a similar compound  $C_6H_5OC_6H_4NO_2H_2SO_4$ .—10. Heated with cholic acid at  $200^\circ$  for 20 hours there is formed a product whence NaOH ppt. amorphous glycoedylsine  $C_6H_5NO_2$  (Lang, *Bl.* [2] 25, 180).—11. Chloroform and KOH form isocyanacetic acid  $C:N.CH_2.CO_2H$  (Calmels, *Bl.* [2] 42, 266).—12. Guanidine carbonate forms the compound  $C_6H_5NO_2(CH_2N_3)_2CO_2aq$  (Nencki & Sieber, *J. pr.* [2] 17, 480).—13. Urea (10 pts.) at  $230^\circ$  forms uric acid (Horbaczewski, *B.* 15, 2678).

**Salts.**—The fact that glycocoil only forms salts with such metals as can displace the hydrogen of amidogen tends to show that the salts have the formula  $CH_2(NHR)CO_2H$ , and not  $CH_2(NH_2)CO_2R$ . Thus it forms no salts with alkalis, and probably none with alkaline earths.

**Barium salt.**—If excess of baryta be added to glycocoil sulphate and the solution be filtered the liquid may perhaps contain glycocoil-barium, but on adding alcohol a pp. is got, which contains variable amounts of glycocoil and baryta. If this pp. be recrystallised from alcohol it becomes pure glycocoil. Hence glycocoil-barium is very unstable, if indeed it exists (Curtius, *J. pr.* [2] 26, 151).

**Zinc salt**  $C_6H_5NO_2Zn$  aq. Partially decomposed by hot water. Boiling  $Na_2CO_3$  removes one-third of the zinc.

**Silver salt**  $AgA'$ . Prepared by heating silver oxide (38 g.) nearly to boiling with a solution of glycocoil (100 g.). The hot liquid is filtered and allowed to cool in the dark. After an hour the liquid is poured off from the silver glycocoil and heated with the remaining silver oxide. This process is repeated until the quantity of silver glycocoil that separates on cooling begins to decrease when a fresh quantity of silver oxide (38 g.) is added to that which still remains,

and the process is continued till all the silver oxide is either used up or reduced to silver. Yield 75 p.c. (Curtius, *J. pr.* [2] 26, 165). Crystallises in tablets. Turns grey in daylight. It is not hygroscopic. It is strongly alkaline. It decomposes at 100°. Warmed with a mixture of benzene and benzoyl chloride it forms silver chloride and the three following acids: (1) Hippuric acid (Dessaignes, *C. R.* 37, 251); (2) an acid  $C_{10}H_7N_3O_2$ : [207°], which when boiled with dilute acids gives benzoic acid and two molecules of glycooll, and hence it may perhaps be written  $Ph.CO.NH.CH_2.CO.NH.CH_2.CO.H$ ; (3) an acid  $C_{10}H_7N_3O_4$ , which blackens at 240° without melting, but with acids gives also benzoic acid and glycooll on boiling (T. Curtius, *J. pr.* 132, 239). Silver glycooll is converted by EtI into  $NEt_2.LCH_2.CO_2Et$ .— $AgA'$ .HOEt. Obtained by ppg. a solution of silver glycooll by alcohol.

Other salts.— $PdA'$ : yellow needles (Drechsel, *J. pr.* [2] 20, 475).— $CdA'$ : aq: silky foliated crystals.— $CuA'$ : aq: blue needles. S. 6 at 15°.— $PbA'$ : aq: needles.— $HgA'$ : aq: small crystals.

Salts with acids.— $HA'HCl$ : deliquescent crystals, v. e. sol. water, sl. sol. alcohol; has an acid, slightly astringent taste.— $H_2A'HCl$ : trimetric crystals:  $a:b:c = 1:1.1108:0.901$ .— $H_3A'H_2PtCl_6$ .— $HA'HNO_3$ : [145°]. Decomposed by fusion (Franchimont, *R. T. G.* 2, 339). Trimetric crystals:  $a:b:c = 1.3:412:2.969$  (Nicklès, *Compt. Chim.* 1849, 256);  $=0.687:750:1$  (Loschmidt, *Sitz. W.* 51 [2] 386). According to Horsford they are monoclinic.— $H_2A'HNO_3$ .— $H_3A'H_2SO_4$ . Large prisms, permanent in the air; sol. water, insol. alcohol and ether. According to Nicklès the crystals are trimetric:  $a:b:c = 1:424:321$ .— $HA'HOAc$  1½ aq: crystallises from water.— $H_2A'H_2C_2O_4$ : trimetric crystals:  $a:b:c = 1:3.072:2.792$  (N.).

Combinations with both acids and bases.— $KA'HCl$ .— $BaA'H_2Cl_2$ : trimetric prisms.— $KA'HNO_3$ : needles (Boussingault, *A.* 39, 310).— $CuA'.Cu(NO_3)_2$ : 2aq: blue needles.— $AgA'HNO_3$ : needles.— $KHA'H_2SO_4$ : prisms.

Acetyl derivative v. ACETURIC ACID.

Benzoyl derivative v. HIPPURIC ACID.

Salicyl derivative v. OXY-BENZOIC ACID.

Methyl ether  $NH_2.CH_2.CO.Me$ . (54°) at 50 mm. Obtained by suspending its hydrochloride in ether, shaking with the theoretical amount of  $Ag_2O$ , evaporating the filtrate, drying over  $BaO$  and fractionally distilling (Curtius a. Goebel, *J. pr.* [2] 37, 165). Liquid, miscible with all ordinary menstrua; boils with decomposition at 180°. It forms a copper salt crystallising in blue needles, v. sol. water.  $Cu(NH_2.CH_2.CO.Me)_2.aq$ . Hydrochloride  $NH_2.CH_2.CO.Me$ . [175°]. Formed by passing dry gaseous  $HCl$  through methyl alcohol containing glycooll hydrochloride in suspension until solution takes place (Curtius a. Goebel, *J. pr.* [2] 37, 159). Prisms, v. sol. cold alcohol. Yields ethylamine when distilled with  $Na_2CO_3$ . Its platinochloride is v. sol. alcohol and water.

Acetyl derivative of the methyl ether v. ACETURIC ACID.

Ethyl ether  $NH_2.CH_2.CO.Et$ . (149°) at 748 mm.; (65°) at 40 mm. V.D. 3.47 (calc. 3.57). Formed by treating its hydrochloride in ethereal solution with  $Ag_2O$  as in the preceding case

(G. a. C.). Formed also from bromo-acetic ether by treatment with silver nitrite and reduction of the resulting nitro-acetic ether (De Forcrand, *C. R.* 88, 974). Colourless liquid, miscible with water, alcohol, ether, benzene,  $CHCl_3$ , and petroleum-ether. Somewhat volatile with steam. Absorbs  $CO_2$ . Does not solidify at  $-20^\circ$ . Gives *n*-propylamine when distilled with  $Na_2CO_3$ . Its copper salt  $Cu(NH_2.CH_2.CO_2Et)_2$  2aq crystallises in blue plates, v. sol. water. Hydrochloride  $NH_2.CH_2.CO_2Et$ . [144°]. Formed by passing dry  $HCl$  into alcohol containing glycooll hydrochloride in suspension until solution occurs (G. a. C.). Long needles; may be sublimed. Its platinochloride forms needles [212°]. Hydroiodide  $NH_2.CH_2.CO_2Et$ . Formed by heating glycooll with alcohol and EtI or even Mel at 120° (Schilling, *A.* 127, 97; Kraut, *A.* 177, 267). Trimetric crystals. With  $Ag_2O$  it gives glycooll, alcohol, and  $AgI$ .—Nitrate  $NH_2(NO_3)CH_2.CO_2Et$ . Crystals (Curtius, *B.* 17, 953).

Acetyl derivative of the ethyl ether v. ACETURIC ACID.

Allyl ether. Hydrochloride  $NH_2.CH_2.CO_2C_3H_7$ . [170°–180°]. Prepared by suspending glycooll hydrochloride in allyl alcohol and passing  $HCl$  until a solution is obtained (G. a. G.). Thin plates, m. sol. cold alcohol.

Isoamyl ether. Hydrochloride  $NH_2.CH_2.CO_2C_5H_{11}$ . From glycooll, isoamyl alcohol, and  $HCl$ . Syrup.

Phenyl ether  $NH_2.CH_2.CO_2C_6H_5$ . From phenyl chloro-acetate and alcoholic  $NH_3$  at 140°. Needles, sol. water, v. sl. sol. alcohol and ether (Prevost, *J. pr.* [2] 4, 379).

Anhydride  $C_2H_4NO$  i.e.  $CH_2 \begin{smallmatrix} \text{NH} \\ \text{CO} \end{smallmatrix} >$  or  $CH_2 \begin{smallmatrix} \text{NH.CO} \\ \text{CO.NH} \end{smallmatrix} CH_2$ . [275°]. Prepared by de-

composing an aqueous solution of the hydrochloride of glycooll ethyl or methyl ether with silver oxide and extracting the mixture with ether chloride and anhydride with hot water, by which the latter is dissolved out and crystallises on cooling (Curtius a. Goebel, *J. pr.* [2] 37, 178). Plates. V. sol. hot water and dilute alcohol. Neutral to litmus. It does not combine with ammonia and the alkali metals, but forms salts with silver ( $C_2H_4AgNO$ ) and copper. It forms a hydrochloride crystallising in long needles [180°], converted by boiling water into glycooll hydrochloride.—Platinochloride  $B'$ , ( $HCl$ ),  $PtCl_2$ , 8aq. Large orange-yellow crystals, m. sol. water, sl. sol. alcohol.

Amide  $NH_2.CH_2.CO.NH_2$ . Amido-acetamide. Formed in small quantity by heating glycooll with alcoholic  $NH_3$  at 160°. It is also one of the products of the action of alcoholic  $NH_3$  on chloro-acetic ether (Heintz, *A.* 148, 190; 150, 87). Obtained from its hydrochloride by treatment with  $Ag_2O$ . Solid; v. e. sol. water; alkaline in reaction. Decomposed by boiling water into  $NH_3$  and glycooll.— $B'HCl$ : monoclinic needles; v. e. sol. water, sl. sol. alcohol.— $B'_2H_2PtCl_6$ .

Ethyl-glycooll v. ETHYL-AMIDO-ACETIC ACID. Phenyl-glycooll v. PHENYL-AMIDO-ACETIC ACID. Nitro-phenyl-glycooll v. NITRO-PHENYL-AMIDO-ACETIC ACID.

Sulpho-phenyl-glycooll v. SULPHO-PHENYL-AMIDO-ACETIC ACID.

**Nitro-tolyl-glycocoll v. NITRO-TOLYL-AMID-ACETIC ACID.**

**GLYCOCOLONIC ACID**  $C_9H_9NO_4$ . A product of the action of conc.  $HClAq$  on glycocholic acid (Strecker, *A.* 67, 26; 70, 166). Formed also by heating glycocholic acid above  $140^\circ$ . Needles (from alcohol). Insol. water and ether, v. sol. alcohol. Decomposed by boiling  $HClAq$  into glycocoll and cholic acid.  $NaA'$ : crystals (from alcohol) (Mulder, *J.* 1847-48, 907).

**GLYCOCYAMINE**  $C_8H_{11}N_3O_2$ , i.e.  $NH_2C(NH_2).NH.CH_2.CO_2H$ . Guanido-acetic acid. Mol. w. 117. 8-8 (Strecker), 44 (Nencki).

**Formation.**—1. By adding a few drops of ammonia to an aqueous solution of glycocoll mixed with cyanamide (Strecker, *C. R.* 62, 1212). 2. By heating an aqueous solution containing glycocoll and guanidine carbonate, glycocyammine and ammonic carbonate are formed (Nencki a. Sieber, *J. pr.* [2] 17, 477); the reaction taking place as follows:  $2C_2H_5NO_2 + (CH_3N_3)_2H_2CO_3 = 2C_8H_{11}N_3O_2 + (NH_4)_2H_2CO_3$ . Probably the guanidine first breaks up into cyanamide and ammonia.

**Properties.**—Transparent needles. Sl. sol. cold, v. sol. hot, water; insol. alcohol. Boiled with cupric acetate it gives microscopic crystals of  $Cu(C_8H_{11}N_3O_2)_2$ .

**Salts.**— $HA'HCl$ : prisms; v. sol. water.— $H_2A', H_3PtCl$ , 3aq.

**Glycocyamidine**  $C_8H_9N_3O$  i.e.

The hydrochloride is obtained by heating glycocyammine hydrochloride to  $160^\circ$  (Strecker). The base may be liberated by boiling this salt with lead hydroxide and water. Laminæ; v. e. sol. water. Has an alkaline reaction. It forms a compound with  $ZnCl_2$  crystallising in needles resembling the corresponding salt of creatinin.— $B'HCl$ : v. sol. water.— $B', H_3PtCl$ , 2aq: needles.

**Reference.**—BENZ-GLYCOCYAMIDINE.

**GLYCODRUPOSE v. CELLULOSE.**

**GLYCODYLSYLIN**  $C_{12}H_{21}NO_4$ . An amorphous powder formed by heating glycocoll with cholic acid at  $195^\circ$  (Lang, *B.* [2] 25, 182). Sl. sol. water, v. sol. ether, v. e. sol. alcohol. Not attacked by alcoholic  $KOH$ . Boiling  $HClAq$  forms glycocoll.

**GLYCOGEN**  $C_6H_{10}O_5$ .

**Occurrence.**—In the liver and in the placenta, entering largely into the constitution of most of the tissues of the embryo (Cl. Bernard, *C. R.* 41, 461; 44, 578, 1925; 48, 77, 763, 884; Sanson, *C. R.* 44, 1159, 1328; 46, 140, 343; Schüz, *C. R.* 48, 880; E. Pelouze, *C. R.* 44, 1321; Bonnet, *C. R.* 45, 139, 578; Kekulé, *C. C.* 1858, 800; Poggiale, *J. Ph.* [8] 84, 99; Harley, *Pr.* 10, 289; Pavy, *P. M.* [4] 17, 142; *Pr.* 10, 528; 11, 90; Gorup-Besanez, *A.* 118, 227; McDonnell, *Pr.* 12, 476; Wittich, *Fr.* 14, 227; Aldehoff, *Z. B.* 25, 187; Manohé, *Z. B.* 25, 169; Chandon, *Pf.* 13, 626; Schmelz, *Z. B.* 24, 180). As much as 11 p.c. has been found in the liver of new-born puppies (Demant, *H.* 11, 142). Occurs also in blood, muscle, spleen, kidneys, pancreas, and brain (Pavy, *Pr.* 32, 418), and in the white and yolk of egg. Glycogen is uniformly distributed throughout the liver, but in the muscles of the heart, where it also occurs, it is unevenly distributed (Cramer, *Zeit. Biol.* 24, 67). Occurs in the urine

in diabetes mellitus (Leube, *C. C.* 1888, 1278). In vesicular cells of the connective tissue of mollusca, such as oysters (Bizio, *C. R.* 62, 675; 65, 175; Blundstone, *Pr.* 38, 442). In the cockroach (*Blatta orientalis*), and in *Bombus mori* (a butterfly) and its chrysalis (Anderlini, *C. C.* 1888, 451). It is present in a large number of fungi, where it seems to take the place of the starch of higher plants (Errera, *C. C.* 1888, 252). It is present in beer-yeast (Errera, *C. R.* 101, 253; Laurent, *C. C.* 1888, 252). Found in ciliated infusoria (Maupas, *C. R.* 101, 1504). When the following substances are introduced into the systems of starved dogs or rabbits no appreciable quantities of glycogen are found in the liver: flosite, mannite, quercite, erythrite, and fats. But glucose, milk-sugar, cane-sugar, levulose, inulin, glycerin, gelatin, and proteids promote the formation of glycogen. It is not clear whether the glycogen is directly formed from these substances or whether their presence promotes its formation from some other source, or hinders its destruction when formed (Von Mering, *Pf.* 14, 274; cf. Forster, *N. Rep. Pharm.* 25, 733; Wolfberg, *Zeit. f. Biol.* 12, 266; Seegen, *Pf.* 40, 48; Chittenden a. Lambert, *Dissertation* 1885). Asparagine, glycocoll, and, above all, ammonium carbonate, when given to rabbits with a carbohydrate diet greatly increase the amount of glycogen in the liver (Röhmman, *Pf.* 39, 21).

**Preparation.**—1. Glycogen is best obtained pure by Brücke's method (*Sitz. W.* 63 [2] 214), which readily separates all proteids from it. A solution of potassio-mercuric iodide is prepared by precipitating mercuric chloride with potassium iodide, washing the precipitate and then saturating a boiling solution of potassium iodide with it. A watery solution of glycogen, mixed with albuminous matters, is prepared by cutting a perfectly fresh liver into pieces about the size of a hazel-nut, and throwing them into boiling water for a couple of minutes, so as to destroy the liver ferment, which would otherwise convert the glycogen into sugar; the pieces are then bruised in a mortar and extracted with boiling water, and the solution is filtered. As soon as the filtrate is cold it is treated alternately with hydrochloric acid and the potassio-mercuric iodide solution as long as these agents produce any precipitate, and after standing for five minutes the solution is again filtered. Alcohol is then added until about 60 p.c. of absolute alcohol is present in the liquid: this throws down the glycogen alone, but more alcohol precipitates other bodies with it. The precipitate is collected on a filter, washed first with weak, then with 90 p.c. alcohol, and finally with ether, and is then transferred to a tile to dry. Glycogen is thus obtained as a snow-white amorphous powder; if impure or not quite dry, it forms a semi-transparent brittle mass.—2. The boiling aqueous decoction of liver is treated with  $ZnCl_2$ ; the filtrate is evaporated and mixed with dilute (60 p.c.) alcohol, acidified with  $HCl$ . The ppd. glycogen is washed with alcohol (Abels, *J. Th.* 1881, 58; *Pf.* 24, 485).

**Properties.**—White mealy amorphous powder. According to Kälz a. Bornträger (*Pf.* 24, 10) at  $100^\circ$  it is  $(C_6H_{10}O_5)_n$ , aq. With water it forms an opalescent solution. On evaporating

this solution the glycogen separates in films. Its aqueous solution is dextrorotatory  $[\alpha]_D$  varying from  $203^\circ$  to  $234^\circ$  according to concentration (Külz, *Pf.* 24, 85; Landwehr, *Z.* 8, 171); but the polariscope may be used in its estimation (Cramer, *Z. B.* 24, 180). It is insol. alcohol. Its ppn. from aqueous solutions by alcohol is greatly promoted by the presence of NaCl and other salts (Külz, *B.* 15, 1800). Charcoal removes it from its aqueous solution. Iodine colours its aqueous solution red. Glycogen does not reduce Fehling's solution. Glycogen dissolves in cold conc.  $H_2SO_4$  forming an amorphous acid. With baryta-water it gives a pp. of  $BaO(C_6H_{10}O_5)_n$ , while lead subacetate forms  $PbO(C_6H_{10}O_5)_n$ .

**Estimation.**—The substance is extracted with hot dilute KOH, the proteids are ppd. from the solution by HCl and potassio-mercuric iodide, and the glycogen is then ppd. by alcohol, dried, and weighed (Külz, *Z. B.* 22, 161).

**Reactions.**—1. *Diastase and saliva* transform it into maltose, a little glucose, and an achroo-dextrin (Musculus a. Mering, *H.* 2, 413; Siegen, *C. C.* 1877, 8). It is not changed to sugar, to any significant extent, by contact with blood (Pavy, *Pr.* 32, 418). Boiling dilute mineral acids convert it into glucose (Külz a. Bornträger, *Pf.* 24, 28).—2. Does not ferment with yeast.—3. Boiling dilute  $HNO_3$  forms oxalic acid.—4. *Bromine* followed by  $Ag_2O$  forms glycoenic acid. 5. Cold conc.  $HNO_3$  forms amorphous 'nitro-glycogen'  $C_{12}H_{19}(NO_2)_3O_{10}$ , insol. water, alcohol, and ether, sol. alkalis and dilute HCl (Lustgarten, *M.* 2, 634).—6. A mixture of fuming  $HNO_3$  and  $H_2SO_4$  forms 'di-nitro-glycogen'  $C_6H_7(NO_2)_2O_5$ , a white powder, insol. water, alcohol, ether, alkalis, and dilute acids, which explodes at  $80^\circ$  to  $90^\circ$ . It is converted by ammonium sulphide into a dextrin which has but slight power of reducing Fehling's solution, and is dextrorotatory  $[\alpha]_D = 194$  at  $27^\circ$  (Lustgarten). 7.  $Ac_2O$  at  $155^\circ$  forms an amorphous tri-acetyl-derivative  $C_6H_7Ac_3O_5$ , insol. water, alcohol, and ether (Schützenberger, *A.* 160, 80).

**Achroo-glycogen**  $C_6H_{10}O_5$ . Obtained from snail's mucin, by treating with 5 to 10 p.c. aqueous KOH, separating proteids by potassio-mercuric iodide, filtering, and ppg. the achroo-glycogen by alcohol (Landwehr, *Z.* 6, 74). Amorphous white tasteless solid, v. sol. water, forming a strongly opalescent solution. It does not reduce Fehling's solution. By treatment with saliva, diastase, or boiling dilute acids it is converted into dextrin and glucose. It differs from glycogen in giving no colour with iodine.

**GLYCOGENIC ACID**  $C_6H_7O_5$ . Formed by treating an aqueous solution of glycogen at  $100^\circ$  with bromine, and then adding  $Ag_2O$  (Chittenden, *A.* 182, 206). Very acid syrup. Is perhaps identical with gluconic acid.— $CaA'$ : minute needles; sl. sol. cold water.— $EaA'$ : 3aq: prisms.— $Pb_2C_6H_7O_5$ — $CoA'$ : 2aq.

**GLYCOL**  $C_2H_4O_2$  i.e.  $CH_2(OH).CH_2(OH)$ . *Ethylene alcohol*. Mol. w. 62.  $[-11.5^\circ]$  (Bouchard, *C. R.* 100, 452). (198° cor.). S.G.  $1.1168$ ;  $d_4^{20} 1.1121$  (Perkin, *C. J.* 45, 504);  $d_4^{15} 1.1072$  (Brühl). M.M. 2.948 at  $15.1^\circ$  (P.).  $n_D^{20} = 1.4825$ .  $R_D = 23.32$ . H.F.p. 100.890 (Th.). H.F.v. 99.160. S.V. 65.6 (Ramsay).

**Formation.**—1. From ethylene iodide by distilling with silver acetate and saponifying the

resulting diacetate  $C_2H_4(OAc)_2$  with solid KOH (Wurtz, *C. R.* 43, 199; *A. Ch.* [3] 55, 400; *A.* 106, 110; *Suppl.* 1, 85).—2. By heating for 2 days in a sealed tube at  $100^\circ$  a mixture of ethylene bromide (60 g.) with potassium acetate (60 g.) and (85 p.c.) alcohol (120 g.), and saponifying the resulting mono-acetate  $CH_2(OH).CH_2OAc$  with potash or baryta (Atkinson, *P.M.* [4] 18, 433). Debus (*A.* 110, 316) recommends saponifying the mono-acetate with water in sealed tubes at  $100^\circ$ . By heating a mixture of ethylene bromide (195 g.), KOAc (102 g.), and dilute alcohol (200 g. of S.G. .82), Demole (*A.* 173, 117) obtained glycol and acetic ether. From 600 g. ethylene bromide Erlenmeyer (*A.* 192, 246) obtained 125 g. glycol.—3. Together with poly-ethylenic glycols by heating ethylene oxide with water (Wurtz).—4. From ethylene chloro-iodide and moist  $Ag_2O$  at  $160^\circ$  to  $200^\circ$  (Maxwell Simpson, *A. Suppl.* 6, 253).—5. Together with NMe, by boiling a conc. aqueous solution of neurine (Wurtz, *A. Suppl.* 6, 200).—6. By heating ethylene bromide (1 pt.) with water (12 pts.) and PbO at  $150^\circ$  (Eltekoff, *B.* 6, 558).—7. From ethylene bromide ( $55\frac{1}{2}$  pts.), water (180 pts.), and  $Ag_2CO_3$  (41 pts.).  $Ag_2O$  and  $Ag_2SO_4$  used instead of  $Ag_2CO_3$  do not give glycol (Beilstein a. Wiegand, *B.* 15, 1868).

**Preparation.**—1. Ethylene bromide (188 g.) is boiled with water (1000 g.) containing  $K_2CO_3$  (138 g.) in solution in a flask with inverted condenser. A large quantity of vinyl bromide escapes. As soon as all the ethylene bromide has disappeared the liquid is evaporated to dryness, and the glycol separated from the KBr by solution in alcohol. The alcohol is then distilled, when the glycol (13 g.) passes over at  $198^\circ$  (Zeller a. Hüfner, *J. pr.* [2] 10, 270). In this process  $Na_2CO_3$  (106 g.) may be used instead of  $K_2CO_3$ , whereby the yield may be increased (to 35 g.), although the product is not so pure (Stempnewsky, *A.* 192, 242).  $BaCO_3$  used instead of  $K_2CO_3$  yields no glycol.—2. By heating ethylene bromide (1 pt.) with water (26 pts.) for 130 hours in sealed tubes at  $100^\circ$ ; the yield being 60 p.c. (Niederist, *A.* 196, 354).

**Properties.**—Colourless liquid, with sweet taste, but no smell. Miscible with water and alcohol; sl. sol. ether. It dissolves KOH,  $Ca(OH)_2$ ,  $CaCl_2$ ,  $NaCl$ ,  $ZnCl_2$ ,  $SbCl_3$ , and  $HgCl_2$ . In a freezing mixture it sometimes solidifies to a mass of crystals.

**Reactions.**—1. When dropped upon platinum black,  $CO_2$  is given off and the metal may even become incandescent. If in this experiment the glycol be diluted with water and the air with  $CO_2$ , glycollic acid is produced by the oxidation. 2. Cold dilute nitric acid forms glycollic acid, at higher temperatures it forms oxalic acid. When glycol diluted with four times its volume of water is placed in a tall vessel and strong nitric acid is introduced so as to form a layer at the bottom, and the whole is kept for some time at  $30^\circ$ , there is formed glycollic acid, glyoxylic acid, and perhaps also glyoxal (Debus, *A.* 110, 316).—3. *Caustic potash* at  $250^\circ$  forms oxalic acid with evolution of hydrogen.—4. By heating with zinc chloride at  $250^\circ$  there is formed aldehyde and crotonic aldehyde (Bauer, *Rep. chim. pure*, 1860, 244).—5. By heating with a large quantity of water at  $210^\circ$  there is also formed

aldehyde (Nevole, *Bl.* [2] 25, 289).—6. By heating with acids it yields ethers by displacement of one or both of its hydroxyls by acid residues (Lourenço, *A.* 114, 122).—7.  $\text{PCl}_5$  gives ethylene chloride (Wurtz, *A.* 104, 174).—8. *Acetyl chloride* forms  $\text{CH}_2\text{Cl}.\text{CH}_2.\text{OAc}$ .—9. By heating with *ammonium chloride* at  $180^\circ\text{--}190^\circ$  for 8 hours there is formed tri-methyl-pyridine (collidine)  $\text{C}_8\text{H}_{11}\text{N}$ ; the yield being 15 to 20 p.c. of the theoretical (Hofmann, *B.* 17, 1905).—10. Heated with fuming  $\text{HCl}$  in a sealed tube at  $100^\circ$  it forms ethylene chloride (Schorlenmer, *C. J.* 39, 143); but when saturated with  $\text{HCl}$  in an open vessel and then distilled the product is glycol chlorhydrin.—11. *Chlorine* forms oily  $\text{C}_2\text{H}_4\text{O}_2$  ( $240^\circ$ ) and a crystalline chlorinated body ( $39^\circ$ ) (c.  $200^\circ$ ) (A. Mitscherlich, *C. R.* 56, 188).—12. An aqueous solution of glycol acidulated with  $\text{H}_2\text{SO}_4$  is converted by electrolysis into  $\text{CO}$ , oxygen, and  $\text{CO}_2$ , together with formic paraldehyde (tri-oxymethylene), formic, acetic, and glycollic acids, and a polymeride of formic aldehyde resembling glucose (Renard, *A. Ch.* [5] 17, 315).—13. By heating glycol (2 pts.) with *soda-lime* (6 pts.) at  $250^\circ$  there is formed an acid  $\text{C}_{12}\text{H}_{10}\text{O}$ , ( $103^\circ$ ) which may be crystallised from ligroin and ether (Stürcke, *A.* 223, 300).—14. When heated with aldehydes  $\text{RCHO}$ , glycol forms ethylene deriva-

tives of the ortho-aldehydes  $\text{RCH} \begin{array}{c} \text{O}.\text{CH}_2 \\ | \\ \text{O}.\text{CH}_2 \end{array}$  (Wurtz,

*Rep. chim. pure*, 1862, 16; Lochert, *A. Ch.* [6] 16, 35). Thus isobutyric aldehyde gives

$\text{PrCH} \begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{O} \end{array} \text{C}_2\text{H}_5$ . ( $125^\circ$ ). S. 10.—15. *Chloral* unites energetically with glycol, and the resulting compound treated with pentachloride of phosphorus gives a compound (S. G. 11-73) which may be  $\text{COCl}.\text{CHClO}.\text{CH}_2.\text{CH}_2.\text{O}.\text{CHCl}.\text{COCl}$  (Henry, *B.* 7, 762). If a mixture of equivalent quantities of glycol and chloral be left to stand for some days, hard transparent crystals of  $\text{C}_6\text{H}_{10}\text{Cl}_2\text{O}_4$  ( $42^\circ$ ), H.F. 15,400, separate (De Forcrand, *C. R.* 108, 618).—16. *Phosgene*  $\text{COCl}_2$  forms

$\text{C}_2\text{H}_4 \begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{O} \end{array} \text{CO}$  ( $39^\circ$ ) ( $236^\circ$ ) crystallising in prisms

sol. water and alcohol, insol. ether (Nembrowsky, *J. pr.* [2] 28, 439).—17. Distillation with *oxalic acid* gives formic acid, and the diformyl derivative of glycol (c.  $174^\circ$ ) (Lorin, *C. R.* 79, 387; *Bl.* [2] 21, 409; 22, 104).—18. *Algæ* (*Spirogyra*) are able to convert glycol into starch (Bokorny, *C. C.* 1888, 858).

**Sodium derivatives.**— $\text{C}_2\text{H}_4(\text{ONa})(\text{ONa})$ . Formed by dissolving sodium in glycol. White crystalline deliquescent substance. Heated with vinyl bromide in a sealed tube it yields ethylene, glycol, sodium bromide, and apparently formic acid. With methyl alcohol it crystallises as  $\text{C}_2\text{H}_4(\text{OH})(\text{ONa})\text{MeOH}$  in brilliant spangles.—With ethyl alcohol:  $\text{C}_2\text{H}_4(\text{OH})(\text{ONa})\text{EtOH}$ .— $\text{C}_2\text{H}_4(\text{OH})(\text{ONa})\text{C}_2\text{H}_5\text{OH}$ . With glycol it forms crystalline  $\text{C}_2\text{H}_4(\text{OH})(\text{ONa})\text{C}_2\text{H}_4(\text{OH})$  (Forcrand, *C. R.* 107, 843, 1160; 108, 240).— $\text{C}_2\text{H}_4(\text{ONa})_2$ . Formed by fusing the preceding with excess of sodium. Deliquescent mass. When distilled with ethylene bromide it yields vinyl bromide, glycol, and  $\text{NaBr}$ . With  $\text{ClCO}.\text{Et}$  in ether it forms  $\text{C}_2\text{H}_4(\text{O}.\text{CO}.\text{Et})_2$  (c.  $226^\circ$ ) (Wallach, *A.* 226, 82).

**Mono-nitrate**  $\text{C}_2\text{H}_4\text{N}_2\text{O}_5$ .

$\text{CH}_2(\text{OH}).\text{CH}_2.\text{ONO}_2$ . S. G. 1.131. From glycol bromhydrin and  $\text{AgNO}_3$  (Henry, *A. Ch.* [4] 27, 243). Liquid, sol. water.

**Di-nitrate**  $\text{C}_2\text{H}_4\text{N}_2\text{O}_8$ , i.e.

$\text{CH}_2(\text{ONO}_2).\text{CH}_2(\text{ONO}_2)$ . S. G. 1.484. From glycol (42 g.), fuming  $\text{HNO}_3$  (100 g.), and  $\text{H}_2\text{SO}_4$  (200 g.) at  $0^\circ$  (H. Champion, *Z.* 1871, 469). Explosive oil.

**Nitrite-nitrate** (?)  $\text{C}_2\text{H}_4\text{N}_2\text{O}_7$ , i.e.

$\text{CH}_2(\text{ONO}).\text{CH}_2(\text{ONO}_2)$ . S. G. 1.47. Formed by passing ethylene into a cooled mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Kekulé, *B.* 2, 329). Oil. Sodium-amalgam forms glycol and gives off all the N as  $\text{NH}_3$ .

**Aceto-nitrate**  $\text{CH}_3(\text{OAc}).\text{CH}_2(\text{NO}_2)$ . S. G. 1.23. From the mono-acetin,  $\text{HNO}_3$ , and  $\text{H}_2\text{SO}_4$  (Henry, *A. Ch.* [4] 27, 259). Oil, v. e. sol. dilute  $\text{HCl}$ .

**Mono-sulphuric acid**

$\text{CH}_2(\text{OH}).\text{CH}_2(\text{OSO}_3\text{H})$ . From glycol and sulphuric acid (Simpson, *A.* 112, 146). Formed also by the action of sulphuric acid on glycol chlorhydrin (Oppenheim, *B.* 3, 785). Its chloride  $\text{CH}_2(\text{OH}).\text{CH}_2(\text{OSO}_2\text{Cl})$  is formed by treating glycol with  $\text{SO}_2\text{Cl}_2$  (Reinhard, *J. pr.* [2] 17, 342). The free acid is unstable, being decomposed by hot water into glycol and  $\text{H}_2\text{SO}_4$ . The potassium salt is hygroscopic. The barium salt  $\text{BaA}'_2$  is v. sol. water, almost insol. alcohol.

**Disulphuric acid**

$\text{CH}_2(\text{OSO}_3\text{H}).\text{CH}_2(\text{OSO}_3\text{H})$ . From glycol and  $\text{ClSO}_3\text{H}$  at  $0^\circ$  (Claesson, *J. pr.* [2] 20, 5). Thick syrup, decomposed by water, especially on warming, into glycol and  $\text{H}_2\text{SO}_4$ . Its salts are insol. alcohol.— $\text{BaA}''$  2aq: hair-like needles.— $\text{K}_2\text{A}''$ : silvery mass.

**Borate**  $(\text{CH}_2(\text{OH}).\text{CH}_2\text{O})_2\text{B}$ . ( $162^\circ$ ). From

glycol by treatment first with gaseous, then with liquid  $\text{BCl}_3$  (Councler, *B.* 11, 1106). Minute laminae, nearly insol. ether. Decomposed by moist air.

**Mono-acetyl derivative**  $\text{C}_2\text{H}_4\text{O}$ , i.e.

$\text{CH}_2(\text{OH}).\text{CH}_2(\text{OAc})$ . *Glycol monoacetin*. Mol. w. 104. ( $182^\circ$ ). Prepared by heating ethylene bromide (1 pt.) with  $\text{KOAc}$  (1 pt.) and 85 p.c. alcohol (2 pts.) at  $100^\circ$  in a closed bottle for two days (Atkinson, *P. M.* [4] 16, 433; *A.* 109, 232; Erlenmeyer, *A.* 192, 246) or by boiling the same mixture with inverted condenser (Maxwell Simpson, *Pr.* 9, 725). The product is fractionally distilled. Glycolic mono-acetin may also be prepared by heating glycol (1 mol.) with  $\text{Ac}_2\text{O}$  (1 mol.) for several hours at  $170^\circ$  (Maxwell Simpson). Colourless liquid, heavier than water. Miscible with water and alcohol. Its aqueous solution is neutral but it is easily decomposed by potash and baryta yielding glycol. Boiling with ethylene bromide and alcohol (S. G. .82) converts it into glycol (Demole, *A.* 177, 45).  $\text{AcCl}$  forms  $\text{C}_2\text{H}_4(\text{OAc})_2$  and  $\text{CH}_2\text{Cl}.\text{CH}_2.\text{OAc}$  (Lourenço, *A.* 114, 127).

**Di-acetyl derivative**  $\text{C}_2\text{H}_4\text{O}$ , i.e.

$\text{CH}_2(\text{OAc}).\text{CH}_2(\text{OAc})$ . *Glycol diacetin*. Mol. w. 146. ( $187^\circ$ ) (Wurtz); ( $190^\circ$ ) (Perkin). S. G. .82 P. 128 (W.);  $\eta$  1.1561 (Brühl);  $\eta$  1.1108;  $\eta$  1.1018 (P.).  $n_D^{20}$  1.4268.  $n_D^{25}$  1.4179 (B.). M.M. 6.454 at  $18^\circ$  (Perkin, *C. J.* 45, 505). V.D. 4.74. S. 14 at  $22^\circ$ . **Rate of formation**: Manschutkin, *B.* 13, 1812.

Formed by heating ethylene bromide or iodide

with silver acetate (Wurtz, *C. R.* 43, 199; *A.* 100, 110; *A. Ch.* [3] 55, 400). From the mono-acetin by heating with  $\text{AcCl}$  in a sealed tube at  $100^\circ$  and fractionally distilling the upper layer of the resulting liquid. Obtained also by heating ethylene bromide with  $\text{KOAc}$  at  $150^\circ$  to  $200^\circ$  (Demole, *A.* 177, 49). Neutral liquid; dissolves in 7 pts. of water at  $22^\circ$ , and is separated by  $\text{CaCl}_2$  from this solution. Miscible with alcohol and ether. Boiling dilute alcohol (S.G. .82) decomposes it into monoacetin,  $\text{HOAc}$ , and  $\text{EtOAc}$ . Resolved by bases into acetic acid and glycol.

*Di-propionyl derivative*  $\text{C}_6\text{H}_{10}(\text{OC}_2\text{H}_5\text{O})_2$ . (211° cor.). S.G.  $\frac{1}{4}$  1.0544;  $\frac{3}{4}$  1.0457. M.M. 8-318 at  $21.2^\circ$  (Perkin, *C. J.* 45, 505).

*Mono-butyryl derivative*  $\text{CH}_3(\text{OH})\text{CH}_2(\text{OC}_2\text{H}_5\text{O})$ . (220°). From glycol (1 mol.) and butyric acid (1 mol.) at  $200^\circ$  (Lourenço, *A. Ch.* [3] 67, 267). Oil.

*Di-butyryl derivative*  $\text{C}_8\text{H}_{16}(\text{OC}_2\text{H}_5\text{O})_2$ . (240°). S.G.  $\frac{1}{4}$  1.024. Obtained by heating ethylene bromide with silver butyrate and a little free butyric acid for several days at  $100^\circ$ , and fractionally distilling the product (Wurtz, *A. Ch.* [3] 55, 400). Oil; sol. alcohol and ether.

*Acetyl butyryl derivative*  $\text{CH}_3(\text{OAc})\text{CH}_2(\text{OC}_2\text{H}_5\text{O})$ . (212°). Formed by heating glycol chloro-acetin  $\text{CH}_2(\text{OAc})\text{CH}_2\text{Cl}$  with silver butyrate at  $110^\circ$ ; or from glycol chloro-butyryl and  $\text{AgOAc}$  at  $150^\circ$ ; in either case the product is digested with ether, and the ethereal filtrate is distilled (Maxwell Simpson, *Pr.* 10, 115). Formed also by heating glycolic mono-acetin with butyryl chloride, or glycolic mono-butyryl with  $\text{AcCl}$  (Lourenço). Heavy oil; sol. alcohol. It is but slowly decomposed by aqueous  $\text{KOH}$  even at  $100^\circ$ .

*Acetyl-valeryl derivative*  $\text{CH}_3(\text{OAc})\text{CH}_2(\text{OC}_2\text{H}_5\text{O})$ . (230°). From glycol mono-acetin and valeric acid (Lourenço, *A.* 114, 122). Neutral oil, sol. alcohol and ether.

*Mono-valeryl derivative*  $\text{CH}_2(\text{OH})\text{CH}_2(\text{OC}_2\text{H}_5\text{O})$ . (240°) (Lourenço, *A. Ch.* [3] 67, 268).

*Di-valeryl derivative*  $\text{C}_8\text{H}_{16}(\text{OC}_2\text{H}_5\text{O})_2$ . (255°).

*Stearyl derivative*  $\text{C}_{18}\text{H}_{37}\text{O}_2$ , i.e.  $\text{C}_2\text{H}_5(\text{OC}_2\text{H}_5\text{O})_2$ . [76°]. From silver stearate and ethylene bromide, the product being extracted with ether (Wurtz, *A. Ch.* [3] 55, 436). Small shining scales, resembling stearin.

*Di-benzoyl derivative*  $\text{C}_{16}\text{H}_{14}\text{O}_2$ , i.e.  $\text{C}_6\text{H}_5(\text{OBr})_2$ . [67°] (above  $860^\circ$ ). Formed by heating silver benzoate (68 g.) with ethylene bromide (29 g.) for several days at  $100^\circ$ , extracting the product with ether, treating extract with alkali lime and rectifying (W.). Trimetric prisms.

*Succinozyl derivative*  $\text{C}_8\text{H}_{10}\text{O}_2$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2\text{O.CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$  (?) [below  $100^\circ$ ]. Formed by heating glycol (1 mol.) with succinic acid (1 mol.) at  $195^\circ$  for 10 hours (Lourenço, *Rep. Chim. pure*, 1860, 179; *A.* 115, 558). Small crystals; sol. water and alcohol, al. sol. ether.

*Succinyl derivative*  $\text{C}_8\text{H}_{10}\text{O}_2$ , i.e.  $\text{C}_2\text{H}_5\text{O.CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$  [below  $90^\circ$ ]. (212°)

Obtained by heating glycol (1 mol.) with succinic acid (1 mol.) at nearly  $800^\circ$ . Small crystals; sol. water and ether, m.

*Mono-ethyl ether*  $\text{C}_4\text{H}_{10}\text{O}_2$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2(\text{OEt})$ . (184°) at 722 mm. S.G.  $\frac{1}{4}$  .926 (Demole, *B.* 9, 745). From mono-sodium glycol  $\text{CH}_2(\text{OH})\text{CH}_2(\text{ONa})$  and  $\text{EtI}$  (Wurtz, *A.* 108, 84).

*Di-ethyl ether*  $\text{C}_6\text{H}_{14}\text{O}_2$ , i.e.  $\text{C}_2\text{H}_5(\text{OEt})_2$ . (123-5°). S.G.  $\frac{1}{4}$  1.799. V.D. 4:10 (calc. 4:09). From the preceding compound by successive treatment with potassium and  $\text{EtI}$  (W.). Colourless oil with ethereal odour. Isomeric with acetal.

*Ethyl-phenyl ether*  $\text{C}_8\text{H}_{10}(\text{OPh})(\text{OEt})$ . (230°). S.G.  $\frac{1}{4}$  1.037 (S.);  $\frac{1}{2}$  1.018 (H.). Formed by the action of alcoholic  $\text{KOEt}$  on phenyl bromo-ethyl oxide  $\text{Ph.O.C}_2\text{H}_4\text{Br}$  (Sabaneff, *Bl.* [2] 41, 253), or on phenyl chloro-ethyl oxide (Henry, *C. R.* 96, 1233).

*Ethylidene ether*  $\text{C}_4\text{H}_8\text{O}_2$ , i.e.  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHMe}$ . (82-5°). S.G.  $\frac{1}{4}$  1.000. V.D. 3:19 (calc. 3:05). Obtained by heating aldehyde with glycol for a week at  $100^\circ$  (Wurtz). Liquid; dissolves in 14 vols. water, but separated from the solution by  $\text{CaCl}_2$  and by  $\text{KOH}$ . Not attacked by  $\text{KOH}$ .  $\text{HNO}_3$  forms oxalic and glycolic acids.  $\text{PCl}_5$  gives aldehyde and  $\text{C}_2\text{H}_5\text{Cl}$ . Bromine gives liquid  $\text{C}_4\text{H}_8\text{BrO}_2$  (c.  $150^\circ$ ), whence dilute  $\text{H}_2\text{SO}_4$  liberates glycol bromhydrin.

*Propylidene ether*  $\text{C}_6\text{H}_{12}\text{O}_2$ , i.e.  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHEt}$ . (106°). V.D. 3:46. S.G.  $\frac{1}{4}$  .98. Obtained by heating propionic aldehyde (1 mol.) with glycol (2 mols.) at  $100^\circ$  in a sealed tube; the yield being 75 p.c. (Lochert, *A. Ch.* [6] 16, 30). Colourless limpid liquid; smelling like propionic aldehyde. Dissolves in 5 vols. water; miscible with alcohol and ether.  $\text{KOH}$  and  $\text{CaCl}_2$  separate it from its aqueous solution. Completely saponified by heating with water at  $130^\circ$ , or by treatment with conc.  $\text{HClAq}$ . Does not reduce ammoniacal  $\text{AgNO}_3$ . Bromine gives a liquid bromo-derivative.

*Isobutylidene ether*  $\text{C}_6\text{H}_{12}\text{O}_2$ , i.e.  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHPr}$ . (125°). V.D. 4:13 (calc. 4:02). S.G.  $\frac{1}{4}$  .964. Obtained by heating isobutyric aldehyde (1 mol.) with glycol (2 mols.) at  $100^\circ$ ; the yield being 70 p.c. (L.). Liquid; dissolves in 6 times its volume of water, miscible with alcohol and ether. Saponified by water at  $130^\circ$ , by conc.  $\text{HClAq}$ , and by dilute  $\text{H}_2\text{SO}_4$ . Does not reduce ammoniacal  $\text{AgNO}_3$ . Bromine gives a bromo-derivative  $\text{C}_6\text{H}_{12}\text{BrO}_2$  (c.  $190^\circ$ ), insol. water, sol. alcohol and ether.

*Isoamylidene ether*  $\text{C}_8\text{H}_{16}\text{O}_2$ , i.e.  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHCH}_2\text{Pr}$ . (145°). S.G.  $\frac{1}{4}$  .944. Prepared like the preceding, using isovaleric aldehyde (L.). Liquid, v. sl. sol. water, v. sl. alcohol and ether. Saponified by water at  $130^\circ$ . Does not reduce ammoniacal  $\text{AgNO}_3$ . Bromine gives a bromo-derivative  $\text{C}_8\text{H}_{16}\text{BrO}_2$  (94° at 10 mm.) which is insol. water, sol. alcohol and ether, and when saponified by dilute  $\text{H}_2\text{SO}_4$  gives bromo-valeric aldehyde. Alcoholic  $\text{KOH}$  attacks the bromo-derivative, removing  $\text{HBr}$  and forming  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CH.OH.CMe}_2$  and a small quantity of  $\text{CH}_2\text{O} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CH.OH(OH).CHMe}_2$ .

**Heptylidene ether**  $\langle \text{CH}_2\text{O} \rangle \text{CH}_2\text{C}_6\text{H}_{13}$  (180°). Formed by heating glycol (3 vols.) with  $\alpha$ -naphthol (1 vol.) at 130°; or from glycol (2 vols.),  $\alpha$ -naphthol (1 vol.), and a trace of HOAc at 180°; the yield being 66 p.c. (Lochert, *Bl.* [2] 48, 337; *A. Ch.* [6] 16, 35). Limpid liquid, smelling like  $\alpha$ -naphthol; v. sl. sol. water. v. sol. alcohol and ether. Completely saponified by water at 130°, or by conc. HClAq. Gaseous HCl does not act on it in the cold, but at 100° it forms glycol chlorhydrin and  $\alpha$ -naphthol, and its polymerides. PCl<sub>5</sub> gives ethylene chloride and  $\alpha$ -naphthol. Bromine gives a liquid mono-bromo-derivative.

**Glycol chlorhydrin**  $\text{C}_2\text{H}_4\text{Cl}_2$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2\text{Cl}$  (130°). Is described as **CHLORO-ETHYL ALCOHOL** on p. 61.

**Glycol chloro-acetin** v. **Acetyl derivative** of **CHLORO-ETHYL ALCOHOL**, p. 61.

**Glycol bromhydrin**  $\text{C}_2\text{H}_4\text{Br}_2$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2\text{Br}$ . **Bromo-ethyl alcohol**. (147°) (H.); (155°) (L.). S.G.  $\approx$  1.66 (H.). Formed, together with di-ethylene glycol, by heating glycol (1 pt.) with ethylene bromide (1 pt.) at 120° in a sealed flask (Lourengo, *Bl.* 1, 77). Formed also by treating glycol with HBr at 100° (Henry, *A. Ch.* [4] 27, 250), and from glycol (3 mols.) and PBr<sub>3</sub> (1 mol.) (Demole, *B.* 9, 48). Liquid.

**Nitrate**  $\text{CH}_2(\text{ONO}_2)\text{CH}_2\text{Br}$ . (165°). S.G.  $\approx$  1.735. From the bromhydrin, HNO<sub>3</sub>, and H<sub>2</sub>SO<sub>4</sub> (Henry, *A. Ch.* [4] 27, 258).

**Acetyl derivatives**  $\text{CH}_2(\text{OAc})\text{CH}_2\text{Br}$ . **Glycol bromo-acetin**. (162°). From glycol mono-acetin and HBr at 100° (Demole, *A.* 173, 121). Liquid, sl. sol. water. Conc. NaOHAq decomposes it, liberating ethylene oxide.

**Bromo-acetyl derivative**  $\text{CH}_2\text{Br.CO.O.CH}_2\text{CH}_2\text{Br}$ . (230°-240°). From glycol chlorhydrin and bromine, the other products being ethylene chloro-bromide, bromo-, and di-bromo-acetic acids, and ethylene bromide (Demole, *B.* 9, 557). Slightly decomposed on distillation.

**Glycol iodhydrin**  $\text{C}_2\text{H}_4\text{IO}$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2\text{I}$ . **Iodo-ethyl alcohol**. Obtained in impure condition from glycol and HI in the cold; but if the temperature is allowed to rise only ethylene iodide results (Maxwell Simpson, *Pr.* 10, 119). More easily prepared by heating the chlorhydrin with excess of powdered KI at 100° for 24 hours (Butlerow a. Ossokin, *A.* 144, 42; 145, 257). Non-volatile liquid, m. sol. water, separated from its aqueous solution by K<sub>2</sub>CO<sub>3</sub>. ZnMe<sub>2</sub>, followed by water gives isopropyl alcohol. ZnEt<sub>2</sub>, followed by water gives sec-butyl alcohol.

**Acetyl derivative**  $\text{CH}_2(\text{OAc})\text{CH}_2\text{I}$ . **Glycol iodo-acetin**. From glycol mono-acetin and HI; or from glycol, HOAc, and HI (Maxwell Simpson, *A.* 113, 123; *Pr.* 10, 116). Oil, which crystallises in tables at a low temperature. KOH gives ethylene oxide.

**Glycol cyanhydrin**  $\text{C}_2\text{H}_4(\text{OH})\text{CN}$ . **Hydracrylonitrile**. (c. 220°). S.G.  $\approx$  1.0588. S. (ether), 2.3 at 15°. From ethylene oxide and HCN (Erlenmeyer, *A.* 191, 273). Miscible with water and with alcohol, insol. CS<sub>2</sub>. HCl (S.G. 1.10) or aqueous NaOH give, on boiling, hydracrylic and acrylic acids.

**Di-ethylene glycol**  $\text{C}_4\text{H}_{10}\text{O}_2$ , i.e.  $\text{HO.C}_2\text{H}_4.\text{O.C}_2\text{H}_4.\text{OH}$ . (245°-250°). S.G.  $\approx$  1.132.

V.D. 3.78 (calc. 3.67). When an excess of ethylene oxide is heated with water in sealed tubes there is formed glycol, di-ethylene glycol, and a small quantity of tri-ethylene glycol (Wurtz, *A. Ch.* [8] 69, 330). By heating oxide of ethylene (1 pt.) with glycol (1 pt.) there are formed di- and tri-ethylene glycols. By heating glycol with ethylene bromide at 115° in sealed tubes glycol bromhydrin, diethylene glycol, other polyethylene glycols, and water are produced; if the temperature of the mixture is allowed to rise above 130° the liquid turns brown and yields the bromhydrins of the various polyethylene glycols (Lourengo, *C. R.* 51, 365). By using glycolic chlorhydrin instead of the bromhydrin the polyathylene chlorhydrins may be obtained. Diethylene glycol may also be obtained from its diacetate by treatment with an alkali. Obtained also by treating glycol mono-acetin with sodium-glycol (Mohs, *Z.* 1866, 495). Sweetish syrup; sol. water, alcohol, and ether. Nitric acid (S.G. 1.42) oxidises it to 'diglycollic acid'  $\text{CO}_2\text{H.CH}_2.\text{O.CH}_2.\text{CO}_2\text{H}$ , glycollic acid, and oxalic acid. Conc. HIAq gives ethylene iodide.

**Mono-formyl derivative**  $\text{CH}_2(\text{OH})\text{CH}_2.\text{O.CH}_2.\text{CH}_2(\text{OCHO})$ . (c. 220°). From the chlorhydrin and nitro-methane by heating for 10 hours at 200° (Pfungst, *J. pr.* [3] 34, 37).

**Di-acetyl derivative**  $\text{CH}_2(\text{OAc})\text{CH}_2.\text{O.CH}_2.\text{CH}_2(\text{OAc})$ . (245°-251°). Formed, together with  $\text{C}_2\text{H}_4(\text{OAc})$ , and the di-acetyl derivatives of other polyethylene glycols, by heating ethylene oxide with glacial HOAc or with Ac<sub>2</sub>O at 100°, and fractionally distilling the product. Formed also from glycol diacetin and ethylene oxide (Wurtz, *C. R.* 50, 1195; *A.* 116, 249).

**Chlorhydrin**  $\text{C}_2\text{H}_4\text{Cl}_2$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2.\text{O.CH}_2.\text{CH}_2\text{Cl}$ . (180°-185°). From ethylene oxide and glycolic chlorhydrin at 140° (Wurtz, *A. Ch.* [8] 69, 338). Also from ethylene oxide and gaseous HCl; and from glycol and glycol chlorhydrin at 140° (Lourengo, *A. Ch.* [3] 67, 290).

**Bromhydrin**  $\text{C}_2\text{H}_4\text{Br}_2$ , i.e.  $\text{HO.C}_2\text{H}_4.\text{O.C}_2\text{H}_4\text{Br}$ . (205°). From glycol and  $\text{C}_2\text{H}_3\text{Br}_2$  at 160° (L.).

**Tri-ethylene glycol**  $\text{C}_6\text{H}_{14}\text{O}_3$ , i.e.  $\text{CH}_2(\text{OH})\text{CH}_2.\text{O.CH}_2.\text{CH}_2.\text{O.CH}_2.\text{CH}_2(\text{OH})$ . (c. 290°). S.G. 1.138. Formed by heating glycol with ethylene oxide (v. *supra*). Thick liquid, miscible with water and alcohol, sl. sol. ether. Oxidised by nitric acid to 'diglycolethylene' acid  $(\text{CO}_2\text{H.CH}_2.\text{O})_2\text{C}_2\text{H}_4$ ; a syrupy acid which crystallises with difficulty and forms crystalline salts:  $\text{KHA}$ .— $\text{CaA}$ . 3 aq.— $\text{AgA}$ .

**Di-acetyl derivative**  $\text{O}_2(\text{C}_2\text{H}_5)_2(\text{OAc})_2$ . (290°-300°). From ethylene oxide (3 mols.) and glycol diacetin. Liquid, miscible with water, alcohol, and ether.

**Chlorhydrin**  $\text{C}_4\text{H}_{10}\text{Cl}_2$ . (222°-232°). From ethylene oxide (2 mols.) and glycolic chlorhydrin (1 mol.). Liquid, sol. water.

\* **Bromhydrin**  $\text{C}_4\text{H}_{10}\text{Br}_2$ . (230°). Slightly decomposed on distillation.

**Tetra-ethylene glycol**  $\text{C}_8\text{H}_{18}\text{O}_4$ , i.e.  $(\text{CH}_2(\text{OH})\text{CH}_2.\text{O})_2\text{C}_2\text{H}_4$ . (306°) (350° at 25 mm.). Formed as above from glycol and ethylene bromide.

**Diacetyl derivative**  $C_8H_{16}Ac_2O_4$ , (above 320°). From ethylene oxide (3 mols.) and glycol diacetin (1 mol.).

**Chlorhydrin**  $C_2H_4Cl_2$ , (262°-272°). Liquid, sol. water.

**Penta-ethylene glycol**  $C_{12}H_{26}O_5$ , *i.e.*  $(CH_2(OH).CH_2.O.C_2H_4.O)_2C_2H_4$ , (281° at 25 mm.). Liquid, sol. water, alcohol, and ether.

**Hexa-ethylene glycol**  $C_{18}H_{38}O_7$ , *i.e.*  $(CH_2(OH).CH_2.O.C_2H_4.O)_3C_2H_4$ , (325° at 25 mm.). Viscid liquid (L.).

**GLYCOLAMIC ACID** *v.* GLYCOLLAMIC ACID.

**DI-GLYCOL-ETHYLENIC ACID** *v.* Tri-ethyl-  
enic GLYCOL.

**GLYCOLIGNOSE** *v.* CELLULOSE.

**GLYCOLINE**  $C_2H_5N_2$ , (155°) S.G. 1.008. A base formed by distilling glycerin (6 pts.) with ammonium chloride in a current of  $NH_3$  (Etard, C. R. 92, 460, 795). Liquid, smelling like pyridine. Miscible with water, alcohol, and ether. With  $EtI$  it forms a compound  $C_2H_5N_2EtI$  crystallising in lemon-yellow needles.  $-C_2H_5N_2HCl$ : needles, *v. e.* sol. water and alcohol.

**GLYCOLLAMIC ACID**  $NH_2.CH_2.CO_2H$  *v.* GLYCOCOLL.

**Diglycolamic acid**  $C_4H_8NO_4$ , *i.e.*  $NH(CH_2.CO_2H)_2$ . **Imido-di-acetic acid**. S. 2.43 at 5°. When chloro-acetic acid is boiled with conc.  $NH_4Aq$  for 12 hours there is formed a mixture of glycooll, diglycolamic acid, triglycolamic acid, and a little glycollic acid. The solution, after being freed from most of the  $NH_4Cl$  by ppn. with alcohol is boiled with  $Pb(OH)_2$ . The pp. thus obtained contains lead triglycolamate (whence the acid may be liberated by  $H_2S$ ), and the solution, freed from lead by  $H_2S$ , is boiled with ppd.  $ZnCO_3$ , when insoluble zinc diglycolamate is formed, zinc glycooll remaining in solution (Heintz, A. 122, 257; 124, 297; 136, 213; 145, 49; 156, 54). Trimetric prisms, insol. alcohol and ether; *m. sol.* water, forming an acid solution. Forms a nitrosamine with nitrous acid.

**Salts.**— $NH_4A$ : prisms, *v. e.* sol. water, insol. alcohol.— $BaHA$ : amorphous, *v. sol.* water.— $CuA$ : 2aq: small blue prisms, *sl. sol.* boiling water.— $PbA$ : slender needles.— $ZnA$ : minute tables, nearly insol. water.— $AgA$ : crystalline pp., insol. water.— $AgA.HNO_3$  4aq: prisms, insol. alcohol.— $H_2A.HCl$ : tables, *v. e.* sol. water, *m. sol.* alcohol.— $H_2A.HNO_3$ .— $(H_2A)_2.H_2SO_4$ : small prisms. Decomposed by water into  $H_2SCl$  and  $H_2A$ .— $H_2A.H_2SO_4$ : formed by boiling the preceding with alcohol.

**Amide**  $C_2H_4N_2O_3$ , *i.e.*  $NH(CH_2.CO.NH)_2$ . Prepared, together with the amide of triglycolamic acid, by heating chloro-acetic ether with ammonia at 60° to 70°, evaporating, washing with ether, dissolving in water, and ppg. the mixed hydrochlorides with alcohol. The amides are liberated by  $Ag_2O$ , and may be separated by alcohol, which dissolves only the amide of diglycolamic acid (Heintz, Z. [3] 5, 161). Trimetric tables (from water); *mp. sol.* water, *sl. sol.* hot, nearly insol. cold, alcohol. Its aqueous solution is alkaline.— $B.HCl$ : prisms (from water), *sl. sol.* alcohol.— $B.H_2PtCl_6$ : six-sided tables (from water), insol. alcohol.— $B.HAuCl_4$ : thin six-sided tables (from water) or long needles (from alcohol).

**Anilide**  $NH(CH_2.CO.NHPh)_2$ , [141°].

Formed by digesting the chloro-acetyl derivative of aniline with alcoholic ammonia at 100°, evaporating, and crystallising from water (P. J. Meyer, B. 8, 1154). Needles; *m. sol.* hot water, *v. sol.* ether and alcohol, *sl. sol.* cold water. When boiled with aqueous  $NaOH$  it gives off aniline. Its nitrate crystallises in needles [172°]. Tommasi (Bl. [2] 22, 3) by the action of alcoholic  $NH_3$  on the chloro-acetyl derivative of aniline at 50° obtained an amorphous compound  $C_8H_9NO_3$ .

**p-Toluide**  $NH(CH_2.CO.NH.C_6H_4)$ , [150°]. From the chloro-acetyl derivative of toluidine and alcoholic  $NH_3$  at 100° (Meyer, B. 8, 1155). Rosettes of long silky needles (from dilute alcohol); *sl. sol.* boiling water, *m. sol.* cold alcohol, *v. sol.* ether.

**Ureide**  $NH(CH_2.CO.NH.CO.NH)_2$ , [195°-200°]. From bromo-acetyl-urea and dry or alcoholic  $NH_3$  at 80°-100° (Mulder, B. 5, 1011). Slender needles; *sl. sol.* cold, *m. sol.* warm, water. *V. sol.* dilute  $HClAq$  and reppd. by  $NH_3$ .— $B.HCl$ : crystals.— $B.H_2PtCl_6$ : needles or prisms.

**Nitrosamine**  $NO.N(CH_2.CO_2H)_2$ , [above 100°]. Small pale yellow tables, *m. sol.* water, alcohol, and ether.— $CaA$ : more *sl. sol.* cold than hot water, nearly insol. alcohol.— $BaA$ : crystalline crusts.— $AgA$ : sparingly soluble prisms (Heintz, A. 138, 301).

**Triglycolamic acid**  $C_6H_{12}NO_6$ , *i.e.*  $N(CH_2.CO_2H)_3$ . S. 134 at 5°. Formed by boiling chloro-acetic acid with  $NH_3$  (*v. supra*), or diglycolamic acid with chloro-acetic acid (Heintz, A. 122, 239; 136, 221; Lüddecke, A. 147, 272; Ziegler, Z. [2] 5, 559). Small prisms. Does not combine with acids. Fuming  $HCl$  at 200° splits it up into diglycolamic and glycollic acids. Nitrous gas does not act on it. Zinc and dilute  $H_2SO_4$  reduce it to ethyl-diglycolamic acid.

**Salts.**— $(NH_4)HA$ : needles.— $K_2HA$ : needles, *v. sol.* water.— $BaHA$ : prisms, *sl. sol.* water.— $Ba_2A$ : 4aq: laminæ, insol. water.— $PbHA$ : 2aq: prisms. S. 3.3.— $Pb_2A$ : laminæ.— $Ag_2A$ : crystalline pp.

**Ethyl ether**  $Et_2A$ , (280°-290°). From the silver salt and  $EtI$  (Heintz, A. 140, 264). Liquid, more *sl. sol.* cold than hot water.

**Amide**  $N(CH_2.CO.NH)_2$ . From the preceding ether and  $NH_3$ . Also from chloro-acetic ether and  $NH_3$ . Rectangular tables (from alcohol); *v. sol.* hot water, *sl. sol.* alcohol. Neutral to litmus.— $B.HCl$ : trimetric prisms (from water).— $B.H_2PtCl_6$ : tables or laminæ, insol. alcohol and ether.— $B.HAuCl_4$ .

**GLYCOLLIC ACID**  $C_2H_4O_3$ , *i.e.*  $HO.CH_2.CO_2H$ . **Oxyacetic acid**. Mol. w. 76. [79°].

**Occurrence.**—In the grease of sheep's wool as the potassium salt; separated therefrom by forming the lead salt, decomposing this with  $H_2SO_4$ , and extracting with ether (Buisine, C. R. 107, 789). Occurs also in the juice of unripe grapes and in the leaves of the wild vine (*Ampelopsis hederacea*) (Erlenmeyer, Z. 1866, 659; Gorup-Besanez, A. 161, 229).

**Formation.**—1. From hippuric acid either by treatment with nitrous acid and decomposition of the resulting benzoyl-glycollic acid by boiling dilute  $H_2SO_4$ , or by treatment with dilute  $H_2SO_4$  and decomposition of the resulting glycooll by

nitrous acid (Soccoloff a. Strecker, *A.* 80, 18).—2. Tartaric acid  $\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CO}_2\text{H}$  is heated to  $180^\circ$ ; the residue, consisting of nearly pure glycollic acid, is dissolved in aqueous KOH, silver nitrate is then added, and the ppd. silver glycolate decomposed by HCl (Dessaignes, *C. R.* 88, 44).—3. From glyoxal by the action of alkalis (Debus) and even of water. Thus, when glyoxal is heated with water at  $150^\circ$ , one-third of it is converted into glycollic acid (De Forcrand, *C. R.* 98, 295).—4. By boiling silver bromo-acetate with water. By boiling iodo-acetic acid with moist  $\text{Ag}_2\text{O}$ , or lead iodo-acetate with water (Perkin a. Duppa, *P. M.* [4] 18, 54). In like manner by boiling chloro-acetic acid with caustic alkalis or by heating crystallised chloro-acetate of potassium or sodium (Kekulé, *A.* 105, 285). By boiling chloro-acetonitrile with lime-water (Beckurts a. Otto, *B.* 9, 1591).—5. By allowing a solution of glycol (1 vol.) in nitric acid (4 vols. of S.G. 1.33) to stand for some days (Wurtz, *C. R.* 44, 1306).—6. Together with other products from propylene glycol by oxidation with  $\text{HNO}_3$ , or with air and platinum black (Wurtz, *C. R.* 45, 306).—7. By placing in a tall cylinder layers of alcohol, water, and conc. nitric acid one above another, and leaving the liquids to mix by diffusion, which they do in about a week (Debus, *A.* 100, 1). Glyoxal, glyoxylic acid, oxalic acid, aldehyde, and acetic acid are formed at the same time.—8. Found in the mother-liquor in the preparation of mercuric fulminate (Cloe, *C. R.* 34, 364; Fahlberg, *J. pr.* [2] 7, 331).—9. By the action of zinc and dilute  $\text{H}_2\text{SO}_4$  on oxalic acid (Schulze, *Z.* 1862, 616, 682; Church, *C. J.* 16, 301).—10. By boiling an aqueous solution of oxalic acid for eight days with zinc (Crommyds, *Bl.* [2] 27, 3; De Forcrand, *Bl.* [2] 39, 310).—11. By the action of nitric acid on acrolein (Claus, *A. Suppl.* 2, 119).—12. When tartaric acid is warmed with conc.  $\text{H}_2\text{SO}_4$  at  $45^\circ$  it gives off  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{SO}_2$ , and the residue contains glycollic and pyruvic acids as well as tartaric and racemic acids. The acids are separated by crystallisation, first of their barium, and then of their calcium, salts (Bouchardat, *C. R.* 89, 99).—13. From acetylene tetrachloride and alcoholic KOH at  $100^\circ$  (Berthelot, *Z.* 1869, 683).—14. From di-chloro-vinyl ethyl oxide and water at  $130^\circ$  (Geuther a. Brockhoff, *J. pr.* [2] 7, 114).—15. Occurs among the products of the action of  $\text{HNO}_3$  on glycerin.—16. Together with gluconic and formic acids, by the action of red  $\text{HgO}$  and baryta-water on glycerin (Herzfeld, *A.* 245, 27). Also from glycerin and  $\text{Ag}_2\text{O}$  (Kiliani, *B.* 16, 2415).—17. By heating cupric acetate (2 pts.) with water (5 pts.) at  $200^\circ$ , cuprous oxide being ppd. (Cazeneuve, *C. R.* 89, 525).—18. By oxidising insulin with  $\text{HNO}_3$  (Kiliani, *A.* 205, 168).—18. From glucose or levulose by oxidation with  $\text{Ag}_2\text{O}$ .

**Preparation.**—1. A solution of 10 grms. of commercial glycerin (85 p.c.) and 6 grms. of  $\text{Ca}(\text{OH})_2$  in 200 c.c. of water is heated on a water-bath with precipitated  $\text{Ag}_2\text{O}$  (prepared from 60 grms. of  $\text{AgNO}_3$ ) for four hours. The liquid is then filtered, saturated with  $\text{CO}_2$ , boiled, again filtered, and evaporated till the calcium glycolate crystallises out; the yield is 4.6 grms. (Kiliani, *B.* 16, 2414).—2. Crude sugar (1 pt.) is heated with 2 p.c. sulphuric acid (20 pts.), the sulphuric acid removed by barium carbonate, and to the filtrate

are added calcium carbonate (2 pts.) and silver oxide (1½ pts.). The mixture is heated to  $80^\circ$  until gas ceases to be evolved; it is then filtered and evaporated, when calcium glycolate separates out (Kiliani, *A.* 205, 191).—3. A few grammes of strong alcohol are gently heated in a capacious vessel, with a small quantity of nitric acid, till the vessel becomes filled with red fumes of nitrous acid; and when the action has been thus set up, about 500 grms. dilute alcohol of 20 per cent., and 440 grms. nitric acid of specific gravity 1.34 are poured in. The reaction, which must be moderated by immersing the vessel in water at  $20^\circ\text{C}$ ., is complete in about 12 hours. The liquid is evaporated in small portions over a water-bath, neutralised with lime and the mixture of glycolate of calcium, glyoxal, and glyoxylate of calcium boiled for several hours with milk of lime, whereby both the glyoxal and the glyoxylic acid are converted into glycollic acid. The hot filtrate freed from excess of lime by carbonic acid yields tolerably pure glycolate of calcium; and by decomposing this salt with oxalic acid, neutralising the filtrate with carbonate of lead, and evaporating, the neutral glycolate of lead is obtained in well-developed crystals. The hot aqueous solution of this salt, decomposed by an equivalent quantity of dilute sulphuric acid, yields a solution of glycollic acid, which may be crystallised by evaporation to a syrup at  $60^\circ$  or  $70^\circ\text{C}$ ., afterwards *in vacuo* over oil of vitriol, and purified by recrystallisation from anhydrous ether (Lautemann, *Kolbe's Org. Chem.*; Drechsel, *A.* 127, 150).—4. By boiling chloro-acetic acid with water or with water and calcium carbonate (Fittig, *B.* 9, 1198; Thomson, *A.* 200, 76; Holzer, *B.* 16, 2955).

**Properties.**—Needles (from water) or plates (from ether). When not quite pure it is deliquescent. V. sol. alcohol and ether. Scarcely extracted by ether from its aqueous solution. Very slightly volatile with steam. When strongly heated it gives off pungent fumes and forms glycolide and formic paraldehyde (Krupeky, *Z.* [2] 5, 177). Conc.  $\text{HNO}_3$  oxidises it to oxalic acid. According to Claus (*A.* 145, 256) it may be reduced to acetic acid by zinc and  $\text{H}_2\text{SO}_4$ . Conc.  $\text{HBr}$  at  $100^\circ$  slowly converts it into bromo-acetic acid (Kekulé, *A.* 130, 11). Glycollic acid yields methane (2 vols.) and hydrogen (1 vol.) when distilled with excess of quicklime (Hanriot, *Bl.* [2] 45, 80; *C. R.* 101, 1156). With chloralide at  $125^\circ$  it slowly forms  $\text{CH}_2\text{O}$ .

$\text{CH}_2\text{O} > \text{CH.CCl}$ , [41°], which forms small crystals, sol. alcohol, ether, and chloroform (Wallach, *A.* 193, 35).

**Salts.**— $\text{NH}_4\text{HA}'_2$ : slender needles; v. sol. water and hot alcohol.— $\text{NaA}'_2$ : small crystals (from water).— $\text{NaA}'_2$  3aq (from dilute alcohol).— $\text{NaHA}'_2$ : silky needles.— $\text{Na}_2\text{C}_2\text{H}_3\text{O}_4$  2aq: small deliquescent needles (De Forcrand, *Bl.* [2] 40, 104).— $\text{LiA}'_2$ : long pointed needles.— $\text{KA}'_2$  3aq: silky needles.— $\text{CaA}'_2$  8aq (Lubavin, *J. R.* 14, 297).— $\text{CaA}'_2$  5aq.— $\text{CaA}'_2$  4aq (Fittig, *J. pr.* [2] 10, 271).— $\text{CaA}'_2$  3aq (Debus; Böttlinger, *A.* 198, 228).— $\text{CaA}'_2$  1½aq: stellate groups of asbestos-like needles; sl. sol. cold water.— $\text{OAA}'_2$ : Obtained by evaporating a solution at  $100^\circ$  (Fahlberg; Carius, *J. pr.* [2] 9, 308). Crusts of small

crystals. S. 1<sup>2</sup> at 10° (Debus, A. 166, 117); 5·8 at 100° (Fahlberg).—CaA', CaCl<sub>2</sub> 6aq: separates from a highly concentrated solution containing the two salts in large octahedra, permanent over sulphuric acid in the exsiccator (Jazukovitoh, Z. 1864, 62).—CaA', CaCl<sub>2</sub> 2aq (Böttlinger). A double calcium salt of glycollic and glyoxylic acids CaC<sub>2</sub>H<sub>3</sub>O<sub>4</sub>(CaC<sub>2</sub>H<sub>3</sub>O<sub>4</sub>)<sub>2</sub> 2aq crystallises from the product of the oxidation of alcohol.—SrA', 5aq: minute slender needles, nearly insol. alcohol (Scheiber, J. pr. [2] 13, 436). S. 3·3 at 19°.—BaA', 2aq: monoclinic prisms. S. 13 at 17°.—MgA', 2aq: extremely thin minute needles. S. 8 at 18° (Scheiber). V. sol. boiling water.—ZnA', 2aq: tufts of needles or prisms. S. 3 at 17°. Readily forms supersaturated solutions (Schulze).—PbA', 2aq: monoclinic crystals resembling gypsum. S. 8 at 15°.—PbA', PbO: from the calcium salt and lead subacetate. Crystalline. S. 0·1.—PbA', PbCl<sub>2</sub>. Formed by adding lead chloride to the ammonium salt (Engel, Bl. [2] 44, 424).—CuA': blue crystals. S. 7 in the cold.—HgA', HgCl<sub>2</sub>: prisms, sl. sol. cold water. Formed by boiling chloro-acetic acid with HgO.—AgA': spangles, sl. sol. cold water; decomposed by boiling water. Insol. alcohol (Kekulé).—AgA', 3aq: large crystals (Dessaignes).—AgA', 3aq: monoclinic laminae (Naumann, A. 129, 278).

**Acetyl derivative** AcO·CH<sub>2</sub>·CO<sub>2</sub>H. From glycollic acid and Ac<sub>2</sub>O at 160° (Senff, A. 208, 277). Small prisms, v. e. sol. water, v. sl. sol. alcohol. Decomposed by alkalis into acetic and glycollic acids.—CaA', 2aq: from acetyl-glycollic ether by boiling with lime (Heintz, A. 123, 325).

**Benzoyl derivative** BzO·CH<sub>2</sub>·CO<sub>2</sub>H. Formed by the action of nitrous acid on hippuric acid (Strecker, A. 68, 54; Strecker a. Soccoloff, A. 80, 18). It may also be prepared by slowly passing chlorine into a solution of hippuric acid in moderately dilute KOH, neutralising with HCl, evaporating and extracting with ether (Gössman, A. 90, 181; Strecker, A. 91, 359). Prisms (from alcohol) or laminae. Sl. sol. cold, m. sol. hot, water; v. sol. alcohol and ether. Melts under water. Gives off benzoic acid when heated strongly. Decomposed by boiling water into benzoic and glycollic acids; this hydrolysis is accelerated by the presence of mineral acids. Sodium-amalgam forms 'benzoic acid' C<sub>6</sub>H<sub>5</sub>O<sub>2</sub> and an acid C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>, which has an odour of excrement, is insol. water and ether, but v. sol. alcohol, and forms gummy BaC<sub>6</sub>H<sub>5</sub>O<sub>2</sub> (Otto, A. 145, 350). Salts.—NaC<sub>6</sub>H<sub>5</sub>O<sub>2</sub> 3aq.—CaA', 2aq.—CaA', 3aq: slender needles. S. 2·36 at 11°; 18·8 at 100°. Readily forms supersaturated solutions. Forms a double salt with CaCl<sub>2</sub>—BaA', 2aq: delicate silky needles.—PbA', 2aq.—(PbA'), PbO 8aq.—(FaA'), (FeO<sub>2</sub>)<sub>2</sub> 81aq: voluminous flesh-coloured pp.—ZnA', 2aq.—AgA'.

**m-Chloro-benzoyl derivative** C<sub>6</sub>H<sub>4</sub>Cl·CO·O·CH<sub>2</sub>·CO<sub>2</sub>H. From m-chloro-hippuric acid and nitrous acid (Otto, A. 122, 164). Waxy crystalline mass, sl. sol. water.

**Methyl ether** HO·CH<sub>2</sub>·CO<sub>2</sub>Me. (161° i.v.). S.G. § 1:1868 (Schreiner, B. 12, 179; A. 197, 1).

**Ethyl ether** HO·CH<sub>2</sub>·CO<sub>2</sub>Et. (160° i.v.). S.G. § 1:1078 (Schreiner). Formed by treating chloro-acetic ether with rather more than an equivalent quantity of sodium glycolate (or of sodium acetate in presence of alcohol) at 140°

(Heintz, P. 114, 440; A. 123, 326; Schreiner, A. 197, 5). Prepared by heating glycolide with alcohol in sealed tubes at 200° (Norton a. Tscherniak, C. Z. 87, 30). Liquid, which dissolves in water forming a neutral solution from which it may be separated by K<sub>2</sub>CO<sub>3</sub>. Boiling alkalis decompose it into alcohol and glycollic acid. With aqueous NH<sub>3</sub>, it forms the amide (*v. infra*). It combines with CaCl<sub>2</sub>. With PCl<sub>5</sub> it reacts in the cold forming chloro-acetic ether (Henry, B. 3, 705); excess of PCl<sub>5</sub> at 150° gives chloro-acetyl chloride. A mixture of HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> forms NO<sub>2</sub>·O·CH<sub>2</sub>·CO<sub>2</sub>Et (181°). S.G. § 1:211 (Henry, A. Ch. [4] 28, 424). Cyanic acid forms the allophanil derivative [144°] of which the corresponding acid melts at 192° (Traube, C. C. 1888, 1435).

**Acetyl derivative of the ethyl ether** AcO·CH<sub>2</sub>·CO<sub>2</sub>Et. (179°). S.G. § 1:009. Prepared by heating chloro-acetic ether with dry NaOAc at 170°. Formed also by the action of alcoholic KOAc on bromo-acetic ether (Gal, A. 142, 370). Formed also by passing chlorine into a cooled alkaline solution of acetic ether (Curtius, B. 17, 1673). Liquid, sl. sol. water. NH<sub>3</sub> converts it into acetamide and the amide of glycollic acid. Solid KOH saponifies it. HBr forms ethyl bromide, HOAc, and bromo-acetic acid. HI, even in the cold, forms EtI, acetic ether, and HOAc.

**Propionyl derivative of the ethyl ether** C<sub>2</sub>H<sub>5</sub>O·O·CH<sub>2</sub>·CO<sub>2</sub>Et. (200°). S.G. § 1:005. From chloro-acetic ether and sodium propionate at 175° (Senff, A. 208, 274). Colourless, strongly refracting, liquid, v. sl. sol. cold water.

**Butyryl derivative of the ethyl ether** C<sub>4</sub>H<sub>9</sub>O·O·CH<sub>2</sub>·CO<sub>2</sub>Et. (206°). S.G. § 1:029. From bromo-acetic ether by heating with potassium butyrate (Gal, Bl. [2] 7, 329).

**Isobutyryl derivative of the ethyl ether** Pr·CO·O·CH<sub>2</sub>·CO<sub>2</sub>Et. (197°). S.G. § 1:024 (Senff, A. 208, 271).

**Carbonyl derivative of the ethyl ether** C<sub>2</sub>H<sub>5</sub>O·i.e. CO(OCH<sub>2</sub>·CO<sub>2</sub>Et)<sub>2</sub>. Carbo-diglycollic ether. (280°). Formed, together with ethyl-chloro-formate and glycolide, when gaseous carbonyl chloride COCl<sub>2</sub> is passed through glycollic ether (Heintz, A. 154, 257). Viscid heavy oil, v. sol. alcohol and ether. Readily decomposed by bases into carbonate and glycolate.

**Carboxy-glycollic ether** C<sub>2</sub>H<sub>5</sub>O<sub>2</sub>·i.e. CO<sub>2</sub>Et·O·CH<sub>2</sub>·CO<sub>2</sub>Et. (c. 240°). Formed by heating chloro-formic ether with glycollic ether (Heintz). Heavy oil, v. e. sol. alcohol and ether.

**Benzoyl derivative of the ethyl ether** C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>·i.e. BzO·CH<sub>2</sub>·CO<sub>2</sub>Et. (287° cor.). S.G. § 1:1509. From chloro-acetic ether and NaOBz at 180° (Andrejeff, A. 183, 284). Also from diazo-acetic ether by heating with benzoic acid (Curtius). Oil.

**Propyl ether** HO·CH<sub>2</sub>·CO<sub>2</sub>Pr. (171° i.v.). S.G. § 1:0640 (Schreiner, A. 197, 1).

**Chloride** HO·CH<sub>2</sub>·COCl. From glycollic acid and PCl<sub>5</sub> (Fahlberg, J. pr. [2] 7, 843). Excess of PCl<sub>5</sub> at 120° gives chloro-acetyl chloride.

**Amide** HO·CH<sub>2</sub>·CONH<sub>2</sub>. (120°). Formed by dissolving glycolide in aqueous ammonia (Heintz, A. 123, 325). Formed also by the action of aqueous NH<sub>3</sub> on glycolic ether. Left as a residue when ammonium tartrate is

heated above 150° (Dessaignes, *C. R.* 38, 47). Crystals (from water). *V.* sol. water, m. sol. alcohol (its isomeride glycolic acid is nearly insol. alcohol). Does form salts with bases. Does not hinder the pptn. of  $\text{Cu}(\text{OH})_2$ . Boiling  $\text{KOH}$  aq converts it into glycollic acid. Dilute  $\text{HCl}$  aq does the same.

**Ethylamide**  $\text{HO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{Et}$ . (250°). From chloro-acetic ether and alcoholic ethylamine (Heintz, *A.* 129, 27). Syrup; miscible with water and alcohol, sol. ether. Decomposed by alkalis, even in the cold, into ethylamine and glycollic acid.

**Anilide**  $\text{HO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NHPh}$ . [108°]. *S.* 6 at 20°; 100 at 100°. From glycollic acid and aniline at 130° (Norton a. Tscherniak, *C. R.* 86, 1332). Monoclinic needles;  $\frac{1}{2}$  e. sol. alcohol and ether.

**Di-bromo-o-toluide**  
 $\text{HO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_3\text{Br}_2\text{Me}$ . [182°]. From its acetyl derivative  $\text{AcO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_3\text{Br}_2\text{Me}$  [172°], which is got by heating the compound  $\text{Br} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_3\text{Br}_2\text{Me}$  with acetamide at 160° (Abenius a. Widmann, *J. pr.* [2] 38, 235). Needles (from alcohol).

**Acetyl derivative of the nitrile**  
 $\text{C}_6\text{H}_5\text{NO}_2$ , i.e.  $\text{AcO} \cdot \text{CH}_2 \cdot \text{CN}$ . (175°). *S.G.* 1.100. From chloro-acetonitrile and alcoholic  $\text{KOAc}$  (Henry, *C. R.* 102, 768). Liquid, smelling like acetic acid. Has a sweetish bitter taste. *M.* sol. water. With  $\text{HCl}$  it yields chloro-acetic acid (?).

**Anhydride v. GLYCOLLIDIN.**

**Methyl derivative**  $\text{MeO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{H}$ . (178°). *S.G.* 1.180. Prepared by dissolving sodium (2 atoms) in methyl alcohol and mixing the solution with chloro-acetic acid (1 mol.). Purified by means of its zinc-salt. Thick syrup, miscible with water. Not decomposed by boiling alcoholic  $\text{NaOH}$ . Salts.— $\text{KA}'$  4aq; large prisms (from water); permanent in the air. Readily forms super-saturated solutions. Sol. alcohol.— $\text{NaA}'$ : deliquescent.— $\text{CaA}'$  2aq; gummy, but becomes crystalline over  $\text{H}_2\text{SO}_4$ .— $\text{BaA}'$ : prisms, *v.* sol. water, nearly insol. alcohol.— $\text{PbA}'$ : crystalline mass, sol. water and alcohol.— $\text{CuA}'$  2aq; greenish monoclinic prisms, sol. water and alcohol.— $\text{ZnA}'$  2aq; acute trimetric octahedra. *S.* 27.4 at 18.4°. Sol. alcohol.— $\text{AgA}'$ : delicate flat needles (from hot water).

**Methyl derivative of the methyl ether**  
 $\text{MeO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Me}$ . (133°) (Schreiner, *B.* 12, 179); (127° i.V.) (Fölsing, *B.* 17, 486). *S.G.* 1.0890 (*S.*). Volatile with steam.

**Methyl derivative of the ethyl ether**  
 $\text{MeO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Et}$ . (139°) (*S.*); (131°) (*F.*). *S.G.* 1.0740.

**Methyl derivative of the propyl ether**  
 $\text{MeO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Pr}$ . (147° i.V.). *S.G.* 1.0552.

**Ethyl derivative**  $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{H}$ . **Ethyl-glycollic acid.** (199°) (Schreiner). Formed by the action of alcoholic  $\text{NaOEt}$  on chloro-acetic acid (Heintz, *P.* 109, 489; 111, 552). The resulting mixture is filtered from  $\text{NaCl}$ , evaporated, dissolved in water, and mixed with cupric sulphate in quantity rather more than equivalent to the sodium used. The mixture is evaporated over the water-bath, and the residue is exhausted with alcohol which extracts cupric ethyl-glycolate. After purification by crystallisation this salt is decomposed by  $\text{H}_2\text{S}$ . Ethyl-glycollic acid

is also formed from  $\text{CH}_2\text{Cl} \cdot \text{COCl}$ , and excess of  $\text{NaOEt}$  (Geuther a. Brockhoff, *J. pr.* [2] 7, 101). Liquid. Partially decomposed on distillation with production of formic paraldehyde. When boiled for a long time with inverted condenser it forms glycollic acid and ethyl-glycollic ether.  $\text{HIAq}$  gives  $\text{EtI}$  and glycollic acid. Salts.— $\text{BaA}'$ : crystallises with difficulty; *v.* sol. water and alcohol.— $\text{CaA}'$  2aq: minute needles (from alcohol-ether).— $\text{CuA}'$  2aq: blue prisms. *S.* 14.2 at 14°.

**Ethyl-derivative of the methyl ether**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Me}$ . (142° i.V.); (148°) (*F.*). *S.G.* 1.0145 (Schreiner, *A.* 197, 1).

**Ethyl derivative of the ethyl ether**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Et}$ . **Ethyl-glycollic ether.** (158°) (*S.*); (152°) (*F.*). *S.G.* 1.1145. Obtained as above; also from chloro-acetic ether and  $\text{NaOEt}$  (Henry, *B.* 4, 706). Formed also by treating  $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Na}$  with alcohol and  $\text{EtI}$ .

**Ethyl derivative of the propyl ether**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Pr}$ . (166° i.V.). *S.G.* 1.0944.

**Ethyl derivative of the isoamyl ether**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{C}_4\text{H}_9$ . (180°–190°). From sodium ethyl-glycolate and isoamyl iodide in alcohol (O. Siemens, *J.* 1861, 452).

**Ethyl derivative of the chloride**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{COCl}$ . (128°). *S.G.* 1.1145. From the acid and  $\text{PCl}_5$  (Henry, *B.* 2, 276).

**Ethyl derivative of the amide**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CONH}_2$ . (225°). From  $\text{EtO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Et}$  and cold  $\text{NH}_3$  aq. Trimetric prisms. Melts below 100°. *V.* e. sol. water, *v.* sol. alcohol and ether. Gives with  $\text{Br}$  and  $\text{KOH}$  aq the urea  $\text{EtO} \cdot \text{CH}_2 \cdot \text{NH} \cdot \text{CO} \cdot \text{NH} \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{OEt}$  [80°] (Holmann, *B.* 18, 2784).

**Ethyl derivative of the nitrile**  
 $\text{EtO} \cdot \text{CH}_2 \cdot \text{CN}$ . (133°). *S.G.* 1.0909. Formed by distilling the amide  $\text{EtO} \cdot \text{CH}_2 \cdot \text{CONH}_2$  (40 g.) with  $\text{P}_2\text{O}_5$  (60 g.) (Norton a. Tscherniak, *C. R.* 87, 277). Liquid, *sl.* sol. water, *v.* sol. alcohol and ether.

**Tri-chloro-ethyl derivative**  
 $\text{CCl}_3 \cdot \text{CH}_2 \cdot \text{O} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{H}$ . (70°). Formed, together with chloro-acetic acid, by warming tri-chloro-ethyl alcohol with aqueous  $\text{KOH}$  (Garzarolli-Thurnlackh, *A.* 210, 71). Small plates (from water). *V.* sol. alcohol, ether, and boiling water.— $\text{CaA}'$  3aq: needles, *m.* sol. water.— $\text{AgA}'$ : needles.

**Propyl derivative of the methyl ether**  
 $\text{PrO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Me}$ . (179° i.V.). *S.G.* 1.0850 (Schreiner).

**Propyl derivative of the ethyl ether**  
 $\text{PrO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Et}$ . (185° i.V.). *S.G.* 1.0760.

**Propyl derivative of the propyl ether**  
 $\text{PrO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Pr}$ . (192° i.V.). *S.G.* 1.0778.

**Isoamyl derivative**  $\text{C}_4\text{H}_9 \cdot \text{O} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{H}$ . (285°). *S.G.* 1.003. From sodium isoamylate, isoamyl alcohol, and chloro-acetic acid (Heintz, *P.* 109, 301). Liquid, *sl.* sol. water, miscible with alcohol and ether.— $\text{NaA}'$  2aq: [190°–200°]; thin rectangular plates (from alcohol); *v.* sol. water and alcohol, insol. ether.— $\text{KA}'$  aq: [200°–210°]; long prisms or thin plates. *Pp.* by adding ether to its alcoholic solution.— $\text{HgA}'$ : [170°]; white powder, *v.* *sl.* sol. water, *sl.* sol. alcohol.— $\text{CuA}'$ : minute bluish-green prisms; *v.* *sl.* sol. water, *m.* sol. alcohol.— $\text{AgA}'$ : slender needles (from water).

**Isoamyl derivative of the ethyl ether**  $\text{C}_4\text{H}_9 \cdot \text{O} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{Et}$ . (212°). From sodium

isoamyl-glycollic acid  $\text{C}_8\text{H}_{15}\text{O}_3\text{CO}_2\text{Na}$  and EtH in alcoholic solution at  $100^\circ$  (Siemens).

*Phenyl derivative*  $\text{C}_6\text{H}_5\text{O}_2\text{C}_2\text{H}_4\text{O}_2$ , *i.e.*

$\text{O}_2\text{H}_2\text{C}_2\text{H}_4\text{CO}_2\text{H}$ . *Phenoxy-acetic acid*. [ $97^\circ$ ]. (285°). S. 1. *Formation*.—1. By heating NaOPh with chloro-acetic acid (Heintz, *J.* 1859, 381).—

2. By heating tri-bromo-ethylene with alcohol, KOH, and phenol at  $170^\circ$  (Sabanejeff & Dworkowitsch, *A.* 216, 284). *Preparation*.—1. Equivalents of phenol (1 part) and chloro-acetic acid are melted together and (300 pts. of) solution of NaOH (S.G. 1.3) is added. The resulting crystalline mass is pressed out, dissolved in water and acidified with HCl. The acid separates as an oil which soon becomes crystalline (Giacosa, *J. pr.* [2] 19, 396).—2. By stirring in an iron pan a concentrated solution of sodic chloro-acetate (12 pts.) with sodic phenylate (10 pts.). As soon as the first reaction is over, the mass is heated, with constant stirring until it becomes pasty. This is dissolved in water before it is quite cold. The acid is thrown down by HCl and crystallised from water (Fritzsche, *J. pr.* [2] 20, 269). The yield is 90 per cent. *Properties*.—White needles (from water). Taste both acid and bitter. Antiseptic. Scarcely volatile with steam. Soluble in ether, glacial acetic acid, benzene and  $\text{CS}_2$ . Etherified on keeping in alcoholic solution for 24 hours. *Reactions*.—1.  $\text{FeCl}_3$  gives a yellow pp.—2. Dilute nitric acid (S.G. 1.19) converts it into di-nitro-phenol.—3. Bromine-water forms  $\text{C}_6\text{H}_4\text{Br.O.CH}_2\text{CO}_2\text{H}$  (Giacosa).—4. Violently attacked by  $\text{PCl}_5$  forming  $\text{PhO.COCl}_2\text{COCl}$  and  $\text{C}_6\text{H}_4\text{Cl.O.CH}_2\text{COCl}$  (Michael, *J. pr.* [2] 35, 96). Salts.— $\text{NaA}'$  3aq. Needles (from alcohol).— $\text{KA}'$ . Scales (F.). Needles (G.).— $\text{NH}_4\text{A}'$ . Scales (F.).— $\text{CaA}'$  3aq.— $\text{BaA}'$  3aq.— $\text{CuA}'$  2aq: sparingly soluble minute prisms.— $\text{AgA}'$ : slender needles grouped concentrically. Methyl ether.— $\text{MeA}'$ . (245° uncor.). S.G.  $\frac{1}{2}$  1.150. Ethyl ether.— $\text{EtA}'$ . (251° uncor.). S.G.  $\frac{1}{2}$  1.104. Amide.— $\text{CH}_3(\text{OPh})\text{CO.NH}_2$ . [ $102^\circ$ ]. From  $\text{NH}_3$  and  $\text{EtA}'$ . Nitrile.— $\text{CH}_3(\text{OPh})\text{CN}$ . (237°). S.G.  $\frac{1}{2}$  1.09. From  $\text{P}_2\text{O}_5$  and the amide. Thio-amide.— $\text{CH}_3(\text{OPh})\text{CS.NH}_2$ . [ $111^\circ$ ]. From the amide and alcoholic sulphide of ammonium. Anilide.— $\text{CH}_3(\text{OPh})\text{CO.NHPh}$ . [ $99^\circ$ ]. Formed by heating phenyl-glycollic acid of aniline to  $150^\circ$ .

*Bromo-phenyl derivative*  
 $\text{C}_6\text{H}_4\text{Br.O.CH}_2\text{CO}_2\text{H}$ . *Bromo-phenyl-glycollic acid*. [ $154^\circ$ ]. Solidifies at  $143^\circ$ . Formed by saponifying its ether. Also from the phenyl derivative and Br. It forms dimetric prisms, v. sol. alcohol, hardly soluble in water. Salts.— $\text{NaA}'$  2aq.— $\text{BaA}'$  1½aq. *Ethyl ether*.— $\text{EtA}'$ . [ $69^\circ$ ]. Solidifies at  $28^\circ$ . From phenyl-glycollic ether (70g.) dissolved in  $\text{CS}_2$  (140g.), cooled to  $0^\circ$ , and treated gradually with bromine (65g.) (Fritzsche, *J. pr.* [2] 20, 295). *Properties*.—Insoluble in water; crystallises from alcohol.

*Chloro-phenyl derivative*  
 $\text{C}_6\text{H}_4\text{Cl.O.CH}_2\text{CO}_2\text{H}$ . [ $163^\circ$ ]. Formed from  $\text{C}_6\text{H}_5\text{O.CH}_2\text{CO}_2\text{H}$  by successive treatment with  $\text{PCl}_5$  and water (Michael, *J. pr.* [2] 35, 96). Prisms.

*o-Nitro-phenyl derivative*  
 $[\text{NO}_2]\text{C}_6\text{H}_3\text{O.CH}_2\text{CO}_2\text{H}$ . [ $187^\circ$ ]. *Preparation*.—*o*-Nitrophenol (80g.), chloroacetic acid (20g.) neutralised with strong NaOH are heated at  $100^\circ$  for 11 hours. The yield is fair (15g.) (A. Thate,

*J. pr.* [3] 29, 146). *Properties*.—Yellowish-white pyramids (not regular octahedra). Doubly refracting. *Reactions*.—1. Reduced in alkaline solution by sodium amalgam to azoxy-, azo-, hydrazo-, and amido-phenyl-glycollic acid successively. The azo-acid  $\text{N}_2[\text{C}_6\text{H}_3\text{O.CH}_2\text{CO}_2\text{H}]_2$  is crystalline [ $162^\circ$ ].—2. Reduced by iron filings and acetic acid to amido-phenyl-glycollic acid, or rather its anhydride  $\text{C}_6\text{H}_4\text{O}_2\text{C}_2\text{H}_4\text{O}_2$  [ $167^\circ$ ]

(Thate, *J. pr.* [2] 25, 268). This anhydride is not affected by  $\text{Ac}_2\text{O}$  at  $180^\circ$ . When heated with zinc dust it yields a very small quantity of a base  $\text{C}_6\text{H}_4\text{NO}$  (c.  $200^\circ$ ) (Duparc, *B.* 20, 1942).—3. Reduced by stannous chloride and HCl to the anhydride of chloro-amido-phenyl-glycollic acid together with variable quantities of the anhydride of amido-phenyl-glycollic acid (Thate). Salts.— $\text{NaA}'$  aq.— $\text{BaA}'$  2aq.— $\text{CuA}'$  2½aq (Fritzsche, *J. pr.* [2] 20, 284).

*o-Nitro-phenyl derivative of the ethyl ether* [ $2:1$ ]  $\text{C}_6\text{H}_3(\text{NO}_2)\text{O.CH}_2\text{CO}_2\text{Et}$ . [ $49^\circ$ ]. Colourless needles, sol. alcohol, ether, and benzene, insol. water (Duparc, *B.* 20, 1942). Reduced by tin and HCl to a base  $\text{C}_6\text{H}_3\text{ClINO}_2$ , which crystallises in long needles [ $195^\circ$ ], sol. alcohol and alkalis, insol. ether.

*p-Nitro-phenyl derivative*  
[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)\text{O.CH}_2\text{CO}_2\text{H}$ . [ $183^\circ$ ]. From sodium *p*-nitro-phenol, sodium chloro-acetate, and caustic soda, each in concentrated solution. The mixture is evaporated, extracted with water, and treated with HCl. The acid is recrystallised from water (F.). Pale yellow plates. May be reduced to very unstable *p*-amido-phenyl-glycollic acid. Salts.— $\text{NaA}'$  3aq.— $\text{BaA}'$  10aq.— $\text{CuA}'$  10aq.

*o-Amido-phenyl derivative*  
 $^*\text{NH}_2\text{C}_6\text{H}_4\text{O.CH}_2\text{CO}_2\text{H}$ . *o-Amido-phenyl-glycollic acid*. This acid splits up at the moment of its formation into  $\text{H}_2\text{O}$  and an anhydride:  $\text{C}_6\text{H}_4\text{O}_2\text{C}_2\text{H}_4\text{O}_2$ . [ $167^\circ$ ]. Solidifies at  $144^\circ$ .

*Preparation*.—*o*-Nitro-phenyl-glycollic acid is reduced by iron filings and dilute (25 p.c.) acetic acid. The product is diluted, filtered, evaporated, and extracted with alcohol. The alcoholic extract is evaporated and the residue crystallised from water (A. Thate, *J. pr.* [2] 29, 178). *Properties*.—White cubes (from dilute alcohol), which nevertheless are doubly refracting. Sickle-shaped needles (from water), composed of small prisms joined in staircase fashion. Sol. ether, benzene, and alkalis. Can not be converted into a chloro-derivative by boiling with HCl. Boiled with alkalis the anhydride forms salts of amido-phenyl-glycollic acid. Salts.— $\text{KA}'$ . Solutions of this salt give with  $\text{BaCl}_2$  no pp. in the cold, a white pp. on boiling; with  $\text{Pb}(\text{OAc})_2$ , a heavy white pp.; with  $\text{AgNO}_3$ , a copious white pp.; with  $\text{FeCl}_3$ , a dark brown pp.; with  $\text{CuSO}_4$ , a crystalline green pp. Acids ppt. the anhydride described above.— $\text{PbA}'$ .— $\text{AgA}'$ .

*Chloro-o-amido-phenyl derivative*  
 $^*\text{C}_6\text{H}_3(\text{NH}_2)\text{Cl.O.CH}_2\text{CO}_2\text{H}$ . *Chloro-o-amido-phenyl-glycollic acid*.

Anhydride  $\text{C}_6\text{H}_4\text{O}_2\text{C}_2\text{H}_4\text{O}_2$  [ $167^\circ$ ].

*Preparation*.—*o*-Nitro-phenyl-glycollic acid is digested at  $100^\circ$  with a solution of  $\text{SnCl}_2$  and HCl

As soon as the liquid is filled with crystals it is allowed to cool, filtered, and recrystallised from alcohol (A. Thäte, *J. pr.* [2] 29, 183). *Properties*.—White silky branching needles, insol. cold water, sl. sol. hot water, ether, and benzene, sol. alcohol. Salts.—KA'. Obtained by digesting the anhydride with KOH. Its solution gives with BaCl<sub>2</sub>, no pp.; Pb(OAc)<sub>2</sub>, white crystalline pp.; with AgNO<sub>3</sub>, white flocculent pp.; FeCl<sub>3</sub>, dark wine-red colour and, after a time, finely-divided cherry-red pp.; CuSO<sub>4</sub>, yellowish-green pp.—NaA'.—AgA'.—PbA'.

*Aldehyde-phenyl derivative* *ω*, vol. I. p. 110.

*p-Tolyl derivative* C<sub>7</sub>H<sub>7</sub>O<sub>2</sub>, i.e. CH<sub>3</sub>.C<sub>6</sub>H<sub>4</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>H. [135°]. From chloroacetic acid, *p*-cresol, and NaOHaq (Gabriel, *B.* 14, 923; Napolitano, *G.* 13, 73). Transparent prisms.—NaA'<sub>2</sub>aq: thin prisms.—NaA'<sub>2</sub>aq: laminæ.—BaA'<sub>2</sub>aq: tables or prisms; sl. sol. cold water.—PbA'<sub>2</sub>aq: laminæ.—AgA'.

*o-Cumyl derivative* C<sub>11</sub>H<sub>13</sub>O<sub>2</sub>, i.e. [2:1]Pr.C<sub>6</sub>H<sub>4</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>H. [130°]. From *o*-isopropyl-phenol, chloroacetic acid, and aqueous NaOH (Fileti, *G.* 16, 129). Needles (from water). Forms a crystalline Ba salt and amorphous Pb and Cu salts.—AgA': white needles.

*p-Cumyl derivative* [4:1]Pr.C<sub>6</sub>H<sub>4</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>H. [81°]. From *p*-isopropyl-phenol, chloroacetic acid, and NaOHaq (Spica, *G.* 10, 248). Silky needles, sol. water, v. sol. alcohol and ether. Unlike its *o*-isomeride, its solution is ppd. by HgCl<sub>2</sub>, by AuCl<sub>3</sub>, and by PtCl<sub>4</sub>.—BaA'<sub>2</sub>aq: micaceous scales, m. sol. hot water.—PbA'<sub>2</sub>aq: scales with hexagonal bases, sl. sol. water, sol. alcohol.

*Thymyl derivative* C<sub>9</sub>H<sub>9</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>H. [148°]. Solidifies at 132°. Formed by adding 30 g. of a solution of NaOH (S.G. 1.34) to a fused mixture of thymol (15 g.) and chloroacetic acid (10 g.). Long needles (from alcohol). Sl. sol. water, v. sol. alcohol and ether. May be distilled with slight decomposition (Saarbach, *J. pr.* [2] 21, 159).—BaA'<sub>2</sub>aq: prisms.—PbA'<sub>2</sub>aq: flocculent pp.

*Ethyl ether of the thymyl derivative* C<sub>9</sub>H<sub>9</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>Et. (290°).

*Amide of the thymyl derivative* C<sub>9</sub>H<sub>9</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>NH<sub>2</sub>. [97°]. V. sol. hot water, alcohol, and ether (Spica, *G.* 10, 245).

*Carvacryl derivative* C<sub>8</sub>H<sub>7</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>H. [149°]. Formed from carvacrol and chloroacetic acid (Spica, *G.* 10, 245). White needles; sl. sol. water, v. sol. alcohol and ether.—BaA'<sub>2</sub>aq: prisms, sol. water.—PbA'<sub>2</sub>aq: gummy mass (by ppn.), or minute prisms (from alcohol).—AgA': minute needles.

*Ethyl ether of the carvacryl derivative* C<sub>8</sub>H<sub>7</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>Et. (299°). Oil.

*Amide of the carvacryl derivative* C<sub>8</sub>H<sub>7</sub>.C<sub>6</sub>H<sub>4</sub>.Me.O.CH<sub>2</sub>.CO<sub>2</sub>NH<sub>2</sub>. [68°]. Sl. sol. cold water, sol. alcohol and ether.

*Eugenyl derivative* C<sub>8</sub>H<sub>7</sub>.C<sub>6</sub>H<sub>4</sub>(OMe).O.CH<sub>2</sub>.CO<sub>2</sub>H. [81°]. Formed by adding 30 g. of solution of NaOH (S.G. 1.34) to a fused mixture of chloroacetic acid (10 g.) and eugenol (10 g.). Forms long satiny needles (from water). Not v. sol. water (L. Saarbach, *J. pr.* [2] 21, 159).—NaA'<sub>2</sub>aq.

(*a*)-Naphthyl derivative

C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>H. [190°]. Formed by heating (*a*)-naphthyl with chloroacetic acid and gradually adding KOHAq (Spica, *G.* 16, 487). The product is diluted with water, acidified with HCl, and the pp. dissolved in aqueous ammonium carbonate to separate the unaltered (*a*)-naphthol. Small pale-red prisms, sl. sol. water, v. sol. ether and alcohol.—KA'<sub>2</sub>aq: long acicular crystals, v. sol. water.—PbA'<sub>2</sub>aq: white crystalline pp.—BaA'<sub>2</sub>aq: white needles.—MgA'<sub>2</sub>aq: pink scales. S. 246 at 28°.

*Ethyl ether of the (a)-Naphthyl derivative* C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>Et. [173°]. Colourless crystals, sol. alcohol and ether. Alcoholic NH<sub>3</sub> gives a crystalline pp. of the amide C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CONH<sub>2</sub>. [155°].

(*β*)-Naphthyl derivative C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>H. [151°]. Prepared in like manner, using (*β*)-naphthol (Spica). Trimetric prisms; v. sl. sol. water, sol. alcohol and ether.—NH<sub>3</sub>A': white unctuous scales [180°].—KA'.—BaA'<sub>2</sub>aq: laminæ.—(PbA'<sub>2</sub>)PbO: white crystalline pp.—MgA'<sub>2</sub>aq. S. 62 at 26°.

*Ethyl ether of the (β)-Naphthyl derivative* C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>Et. [49°]. Large transparent scales; converted by alcoholic NH<sub>3</sub> into the amide C<sub>10</sub>H<sub>7</sub>.O.CH<sub>2</sub>.CO<sub>2</sub>NH<sub>2</sub>. [147°].

*Tolylene derivative* Me.C<sub>6</sub>H<sub>4</sub>(O.CH<sub>2</sub>.CO<sub>2</sub>H)<sub>2</sub>. [217°]. From orcin (62 grms.), chloroacetic acid (100 grms.), and caustic soda solution (540 grms. of 31 per cent.). The reaction is violent (Saarbach, *J. pr.* [2] 21, 162). Thin crystals (from water). Sl. sol. water, v. sol. alcohol and ether. Its solutions give an orange pp. with FeCl<sub>3</sub>.—NaA'<sub>2</sub>aq. V. sol. water. Needles (from alcohol).—KA'<sub>2</sub>aq.—CaA'<sub>2</sub>aq. Ethyl ether.—EtA'. [107°]. Amide.—Me.C<sub>6</sub>H<sub>4</sub>(O.CH<sub>2</sub>.CONH<sub>2</sub>)<sub>2</sub>. Amorphous.

*Nitro-tolylene derivative* Me.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)(OCH<sub>2</sub>.CO<sub>2</sub>H)<sub>2</sub>. [140°]. Formed by the action of HNO<sub>3</sub> (S.G. 1.12) at 100° on the tolylene derivative. Crystallised from alcohol (Saarbach, *J. pr.* [2] 21, 163).

*Pyrogallyl derivative* C<sub>3</sub>H<sub>3</sub>(OCH<sub>2</sub>.CO<sub>2</sub>H)<sub>3</sub>. [198°]. S. 1.3 at 15°. Formed by melting pyrogallol (12 pts.) with chloroacetic acid (30 pts.) and then boiling with (200 pts. of) solution of soda (S.G. 1.3), and acidifying when cold (Giacomini, *J. pr.* [2] 19, 398).—KA'.—KH<sub>2</sub>A'aq.

Diglycollic acid C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, i.e. O(CH<sub>2</sub>.CO<sub>2</sub>H)<sub>2</sub>. *Paramalic acid*. Mol. w. 184. [148°]. R<sub>2</sub> 41.90 in a 14 p.c. aqueous solution (Kanonnikov).

*Formation*.—1. Occurs in the preparation of glycollic acid from chloroacetic acid by boiling with aqueous NaOH (Heintz, *P.* 109, 470), with alkaline earths, and with water and PbO or magnesia (Schreiber, *J. pr.* [2] 13, 436).—2. By oxidising di-ethylenic glycol with nitric acid or platinum-black (Wurtz, *C. R.* 5, 182).—3. A by-product in the preparation of glycollic acid by heating glycollic acid to 220° (Heintz, *P.* 116, 280, 452).

*Properties*.—Thick prisms (containing aq). Has no action on light. V. sol. water and alcohol. On distillation it gives formic paraldehyde and other products (Heintz, *A.* 128, 129). By heating with HClaq it is successively converted into glycollic and acetic acids. Fuming HClaq at 185° yields glycollic acid (Heintz, *A.*

180, 257). Potash-fusion gives oxalic and acetic acids.  $\text{PCl}_5$  forms chloro-acetyl chloride.

**Salts.**—The neutral alkaline salts are easily soluble in water, other diglycolates are but sparingly soluble.— $\text{NH}_4\text{HA}'$ : long monoclinic prisms, insol. alcohol. S. 8-26 at  $10^\circ$ .— $\text{KHA}'$ : trimetric crystals, sl. sol. water.— $\text{KA}'$ : long deliquescent needles.— $\text{NaHA}'$ : small tables, sl. sol. water, insol. alcohol.— $\text{NaKA}'$ : small tabular prisms with nacreous lustre, insol. alcohol. [100°].— $\text{LiA}'$ : 5aq. S. 45 at  $18.5^\circ$ .— $\text{LiA}'$ : 2½aq (Schreiber, *J. pr.* [2] 18, 436).— $\text{BaHA}'$ : hard granular crystals.— $\text{BaA}'$ : white crystalline pp. S. 17 at  $100^\circ$ .— $\text{CaA}'$ : 6aq: long shining needles. Much less soluble than calcium glycolate.— $\text{CaA}'$ : 5aq.— $\text{CaA}'$ : 3aq.— $\text{CaA}'$ : 4aq.— $\text{SrA}'$ : 5aq.— $\text{SrA}'$ : 4aq: limpid, non-efflorescent crystals.— $\text{MgA}'$ : 3aq: small prisms.— $\text{PhA}'$ : minute crystals, sl. sol. water.— $\text{CuA}'$ : 4aq: blue crystalline pp.— $\text{ZnA}'$ : 3aq.— $\text{AgA}'$ : white granular pp.

**Ethyl ether EtA'**. (240°). From the silver salt and EtI (Heintz, A. 144, 95). Also from chloro-acetic ether, sodium glycolate, and  $\text{Na}_2\text{CO}_3$  at  $190^\circ$  (Heintz, A. 147, 200). Heavy oil. Decomposed by boiling water into alcohol and diglycolic acid. Alcoholic  $\text{NH}_3$  forms the amide  $\text{O}(\text{CH}_2\text{CONH}_2)_2$ .

**First Amide**  $\text{NH}_2\text{COCH}_2\text{OCH}_2\text{CO}_2\text{H}$ . **Diglycolamic acid**. [135°]. Formed by heating the imide with baryta-water. Formed also by heating the second amide with water at  $100^\circ$  (Heintz, A. 128, 140). Trimetric prisms; m. sol. hot water, sl. sol. alcohol, nearly insol. ether.— $\text{BaA}'$ : 2aq: crystals; sl. water.

**Second Amide**  $\text{O}(\text{CH}_2\text{CONH}_2)_2$ . From the ether and cold alcoholic  $\text{NH}_3$ . Trimetric prisms; v. e. sol. hot water, v. sl. sol. alcohol. HCl decomposes it into  $\text{NH}_3$  and diglycolic acid.

**Imide**  $\text{O} < \text{CH}_2\text{CO} > \text{NH}$ . [142°]. S. 1-8 at  $14^\circ$ . Formed by distilling the preceding. Formed also by distilling acid ammonium diglycolate. Long needles.— $\text{AgC}_4\text{H}_7\text{NO}_2$ : laminæ.

**Triglycolic acid**  $\text{C}_3\text{H}_5\text{O}_4$ . A syrupy acid, said to be formed by the action of  $\text{Cl}_2\text{O}$  on a mixture of  $\text{Ac}_2\text{O}$  and iodine (Schützenberger, C. R. 66, 1840).— $\text{CaA}'$ : 2aq: prisms.

**GLYCOLLIC ALDEHYDE**  $\text{C}_2\text{H}_3\text{O}_3$  i.e.  $\text{HOCH}_2\text{CHO}$ . It is doubtful whether this substance has been obtained. It is described by Abelson (A. 164, 213, 223) as a syrup, sol. ether, readily oxidised by  $\text{Ag}_2\text{O}$  to glycollic acid, and obtained by treating  $\text{CH}_3\text{CHClOEt}$  with water at  $115^\circ$ . Abelson obtained the same body by treating  $\text{CH}_3(\text{OH})\text{CHClOEt}$  with conc.  $\text{H}_2\text{SO}_4$ . Glycollic orthoaldehyde  $\text{CH}_3(\text{OH})\text{CH}(\text{OH})_2$ .

**Di-ethyl derivative**  $\text{CH}_3(\text{OH})\text{CH}(\text{OEt})_2$ . (167°). V.D. 66.6 (calc. 67). From  $\text{CH}_3\text{Br}\cdot\text{CH}(\text{OEt})_2$  by heating with alcoholic KOH for twelve hours at  $170^\circ$  (Pinner, B. 5, 150). Fragrant liquid. Decomposed by cold conc.  $\text{H}_2\text{SO}_4$  and by gaseous HCl.  $\text{Ac}_2\text{O}$  at  $120^\circ$  yields a liquid resembling aldehyde, which may be glycollic aldehyde.

**Tri-ethyl derivative**  $\text{CH}_3(\text{OEt})\text{CH}(\text{OEt})_2$ . (164°) (P.); (168°) (L). S.G. 1.892. From bromo-acetal and  $\text{NaOEt}$  at  $160^\circ$ . Also from  $\text{CH}_3\text{Cl}\cdot\text{CHClOEt}$  and  $\text{NaOEt}$  at  $150^\circ$  (Lieben, A. 146, 196). Fragrant liquid.

**GLYCOLLIDE**  $\text{C}_2\text{H}_3\text{O}_3$  i.e.  $\text{CH}_2 < \text{CO} > \text{O}$   $\pi$

$\text{CH}_2\text{O}\cdot\text{CO}$   
|  
 $\text{CO}\cdot\text{O}\cdot\text{CH}_2$  [220°] (N. A. T.); [180°] (D.).

**Formation.**—1. By heating glycollic acid to  $240^\circ$ , small quantities of diglycolic acid and of formic paraldehyde being formed at the same time (Heintz, P. 115, 452).—2. By heating anhydrous potassium chloro-acetate at  $115^\circ$  (Kekulé, A. 105, 288). If the crystallised salt be used most of the glycolide unites with water forming glycollic acid.—3. Glycolide was first obtained by heating tartaric acid to  $180^\circ$  as long as  $\text{CO}_2$  escapes; after a few days the product solidified, and is then washed with hot water (Dessaignes, C. R. 38, 46).

**Preparation.**—A. alcoholic solution of chloro-acetic acid is added to a solution of sodium in 15 times its weight of dry alcohol; anhydrous chloro-acetate of sodium is added, and after drying at  $100^\circ$ , this salt is gradually heated to  $150^\circ$  and kept for two days at that temperature. The product is freed from  $\text{NaCl}$  by washing with water, and may be dried at  $200^\circ$  (Norton a. Tscherniak, C. R. 86, 1332).

**Properties.**—Light white powder; neutral to litmus. Sl. sol. hot nitrobenzene. Dissolves in caustic potash, forming potassium glycolate. Ammonia forms the amide of glycollic acid. Ethylamine forms  $\text{HOCH}_2\text{CO}_2\text{NH}_2$ . Aniline at  $130^\circ$  gives  $\text{HOCH}_2\text{CO}_2\text{NHPh}$ . [108°].

Another anhydride of glycollic acid  $\text{C}_2\text{H}_3\text{O}_3$ . [130°]. Obtained by heating glycollic acid at  $100^\circ$  for a long time (Drechsel, A. 127, 154). Also from glycollic acid and the vapour of  $\text{SO}_2$  (Fahlberg, *J. pr.* [2] 7, 836). Powder, insol. ether, alcohol, and cold water. Boiling water forms glycollic acid. Further heating converts this anhydride into glycolide.

**GLYCOLLURIC ACID** v. HYDANTOIC ACID.

**GLYCOLLYL-AMIDO-BENZOIC ACID**

$\text{CH}_3\text{OH}\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . [212°]. From m-amido-benzoic acid and glycollic acid at  $150^\circ$  (Pelizzari, A. 232, 153). Needles (from water). Sol. alcohol, sl. sol. ether.

**Acetyl derivative**

$\text{CH}_3(\text{OAc})\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . [198°].

**Anhydride.**— $\text{CH}_2 < \text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H} > \text{CO}_2\text{H}$ . [248°]. From  $\text{CH}_3\text{OH}\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  by heat.

**GLYCOLLYL-UREA** v. HYDANTOIN.

**GLYCOLURIL** v. ACETYLENE-UREA, vol. i. p. 44.

**GLYCOSE** v. SUGAR.

**GLYCOSINE**  $\text{C}_2\text{H}_3\text{N}$  i.e.

$\begin{array}{c} \text{CH}-\text{NH} \\ \diagup \quad \diagdown \\ \text{CH}-\text{N} > \text{C} < \text{N}-\text{CH} \end{array}$  **Diglyoxaline.**

**Formation.**—1. By acting on glyoxal with ammonia (Debus, A. 107, 199; Japp a. Clemmshaw, C. J. 51, 553).—2. From tri-chloro-lactic acid and conc.  $\text{NH}_4\text{Aq}$  (Pinner, B. 17, 2000).

**Properties.**—White needles (from alcohol), v. sl. sol. alcohol.

**Salts.**— $\text{B}^+\text{H}_2\text{PtCl}_6$ : buff-coloured needles.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{H}(\text{PtCl}_6)_2$ : deep-yellow crystals, stable at  $120^\circ$ .— $\text{B}^+\text{AgNO}_3$  (Wys, B. 10, 1375).— $\text{B}^+(\text{H}_2\text{C}_2\text{O}_4)_2$ : small nodules, m. sol. cold water.

**Di-benzyl-glycosine**  $C_{14}H_{16}N_2(C_6H_5)_2$ . [145°]. Formed by heating glycosine with benzyl chloride and extracting the product with dilute hydrochloric acid (Japp & Cleminshaw, *C. J.* 51, 555). Colourless plates, v. sol. benzene, sl. sol. petroleum ether.

**Tetra-phenyl-glycosine**

Formed by acting on a mixture of benzil and glyoxal with ammonia (Japp & Cleminshaw, *C. J.* 51, 553). White felted needles, m. sol. hot, sl. sol. cold, alcohol, v. sol. HOAc.

**GLYCOSURIC ACID.** [140°]. Occurs in urine in disease (Marshall, *Ar. Ph.* [3] 25, 593). Prisms; v. sol. water, alcohol, and ether, insol. benzene and light petroleum. Reduces Fehling's solution more strongly than glucose. An ethereal solution becomes red on evaporation.  $\text{FeCl}_3$  gives a transient blue colour.

**GLYCURONIC ACID**  $C_6H_{10}O_7$ .

**Formation.**—1. Euxanthic acid (which occurs in pure or Indian yellow) is split up by heating with HCl or with dilute (3 p.c.)  $\text{H}_2\text{SO}_4$  into glycuronic acid and euxanthone (Spiegel, *B.* 15, 1965; Kütz, *Z. B.* 23, 475; Beyer, *A.* 155, 257; Thierfelder, *H.* 11, 388). The decomposition is best effected by water at 125°.—2. By boiling (a-) or (β-) camphoglycuronic acid with dilute (5 p.c.) HCl (Schmiedberg & Meyer, *H.* 3, 422).—3. By boiling urochloralic acid with dilute  $\text{H}_2\text{SO}_4$  (Mering, *H.* 6, 489).—4. When a rabbit is treated with *tert*-amyl alcohol its urine contains 'di-methyl-ethyl-carbinol-glycuronic' acid  $C_{11}H_{20}O_8$ , which is split up by boiling dilute  $\text{H}_2\text{SO}_4$  into *tert*-amyl alcohol and glycuronic acid. *Tert*-butyl alcohol acts in like manner (Thierfelder & Mering, *H.* 9, 515).

**Properties.**—Syrupy acid, v. sol. alcohol. On evaporation of its solution, or even on standing, it changes to the crystalline anhydride. Gives on oxidation camphoric and formic acids. Bromine converts it into saccharic acid (Thierfelder, *B.* 19, 3148). Sodium-amalgam reduces it to gluconic acid. Its K salt dissolved in 90 p.c. alcohol reacts with aniline forming  $\text{NPh} \cdot \text{C}_6\text{H}_4\text{O}_6\text{K}$ , the potassium salt of the 'anilide of glucose' [177°]. *m*-Tolylene-diamine forms, in like manner,  $\text{C}_6\text{H}_4(\text{N} \cdot \text{C}_6\text{H}_4\text{O}_6\text{K})_2$ . Conc. KOH aq decomposes glycuronic acid, forming oxalic acid, pyrocatechin, and a little protocatechuic acid. Glycuronic acid gives lactic and acetic acid when fermented in presence of cheese and chalk.— $\text{KA}'$ : needles.— $\text{BA}_2'$ : amorphous, y. sol. water.

**Anhydride**  $C_6H_8O_6$ . [167°].  $[\alpha]_D = 19.25^\circ$  at 18°. Monoclinic tables, with sweet taste. V. e. sol. water, insol. alcohol. Dextrorotatory. Reduces hot Fehling's solution. 90 p.p. reduce as much as 1 pt. of glucose. Hinders the ppn. of cupric hydroxide by alkalis.

**Benzoyl derivative**  $C_{12}H_{12}O_8$ . [107°]. Obtained by treating the acid (1 mol.) with  $\text{BzCl}$  (9 mols.) and NaOH (12 mols.) in a 10 p.c. solution (Thierfelder, *H.* 13, 275). V. sol. alcohol. Reduces Fehling's solution.

**Phenyl-hydrazide**  $C_{12}H_{12}N_2O_8$ . [115°]. From the K salt and phenyl-hydrazine mixture. Yellow needles.

VOL. II.

**GLYCYRRHIZIC ACID**  $C_{41}H_{58}O_{16}$ . The sweet principle of *Smilax glycyrrhiza*. Extracted from the leaves and stem by alcohol, the extract being evaporated and the residue dissolved in water and extracted with ether (Wright & Rennie, *C. J.* 89, 237; 49, 857). Crystallises from wet ether with 3 aq. and from water in prisms containing 4 aq. Has no definite melting-point. Sl. sol. cold water, v. sol. hot water and alcohol, m. sol. ether. Insol. chloroform, benzene, and light petroleum. Dissolves in aqueous KOH, the solution turning red in air. Does not reduce Fehling's solution. Is ppd. by lead subacetate. Boiling dilute  $\text{H}_2\text{SO}_4$  converts it into phloretin  $C_{15}H_{14}O_6$  and isodulcitol  $C_{12}H_{22}O_{11}$ .

**GLYCYRRHIZIC ACID**  $C_{41}H_{58}NO_{16}$ . Occurs, probably in combination with ammonia, in the liquorice root (*Glycyrrhiza glabra* and *G. echinata*) (Vogel, *jun.*, *J. pr.* 28, 1; Lade, *A.* 59, 224; Gorup-Besanez, *A.* 118, 236; Hirsh, *Ph.* [3] 1, 749; Roussin, *Ar. Ph.* [3] 8, 156; Robiquet, *A. Ch.* [4] 72, 143; Sestini, *G.* 8, 454; Habermann, *A.* 197, 105). Occurs also in large quantities in the rhizomes of *Polyopodium vulgare* and of *P. semipennatifidum*, both of which ferns are used as substitutes for liquorice (Guignet, *C. R.* 100, 151). Habermann finds in liquorices, besides glycyrrhizic acid, a brown resin, which yields *p*-oxy-benzoic acid when fused with potash, and an amorphous bitter substance  $C_{25}H_{30}NO_{11}$ , sl. sol. water and ether, v. sol. HOAc and aqueous  $\text{Na}_2\text{CO}_3$ .

**Preparation.**—1. The dried and powdered root is extracted with dilute acetic acid; alcohol is added; and the filtrate evaporated to a syrup and washed with water (Guignet).—2. The root is extracted with boiling water containing a little milk of lime; the concentrated extract is ppd. with HOAc. The gelatinous pp. is dissolved in 50 p.c. alcohol, deodorised by charcoal, and evaporated at 100° (Sestini).—3. Commercial 'Glycyrrhizin ammoniacale' is boiled with glacial acetic acid and filtered while hot. The acid ammonium salt then crystallises from the filtrate (Habermann). The acid may be obtained by conversion into the lead salt and decomposing by  $\text{H}_2\text{S}$ .

**Properties.**—Gelatinous mass (from hot aqueous solution). When dry it forms an amorphous solid, which swells up in cold water. V. sl. sol. ether and alcohol, sol. boiling HOAc. Turns brown at 100°. It has a sweet taste and an acid reaction. Expels  $\text{CO}_2$  from  $\text{CaCO}_3$ , suspended in hot water. Reduces Fehling's solution on heating. Boiling dilute acids split it up into glycyrrhetin and parascorbic acid  $C_6H_8O_6$ .

**Salts.**— $\text{NH}_4\text{A}'''$ : laminae (from alcohol or HOAc); prepared as above. Insol. ether, sl. sol. alcohol, v. e. sol. boiling water. Separates from dilute alcohol or hot water as a gelatinous form.— $(\text{NH}_4)_2\text{A}'''$ : amorphous gummy mass, v. sol. water, insol. alcohol. Has an intensely sweet taste.— $\text{KHA}'''$ : crystalline grains. Swells up in cold water, forming a jelly; v. sol. hot water, v. sl. sol. alcohol. Extremely sweet.— $\text{K}_2\text{A}'''$ : yellowish amorphous mass; v. sol. water, v. sl. sol. alcohol. From its solution in HOAc the salt  $\text{KH}_2\text{A}'''$  crystallises out.— $\text{Ba}_2\text{A}'''$ : flocculent pp.— $\text{Pb}_2\text{A}'''$ : yellowish-brown mass, sl. sol. water, insol. alcohol, sol. HOAc.

TT

**Glyoxyrrhizin**  $C_{12}H_{10}NO_4$ . [200°]. Formed by boiling glyoxyrrhizic acid with dilute acids (Habermann, *B.* 10, 870; Griessmeyer, *D. P. J.* 209, 228). Crystalline powder; has no taste. Insol. water, ether, and alkalis; sol. alcohol, HOAc, and  $H_2SO_4$ . Does not give *p*-oxy-benzoic acid on potash-fusion (Habermann; cf. Weselsky & Benedikt, *B.* 9, 1158).

**Di-acetyl derivative**  $C_{22}H_{18}Ac_2NO_4$ . [217°]. From glyoxyrrhizin and AcCl. Crystalline powder; insol. water. Gives on oxidation amorphous  $C_{22}H_{18}NO_4$ .

**Bromo-glyoxyrrhizin**  $C_{12}H_{10}BrNO_4$ . From glyoxyrrhizin and Br in HOAc. Crystalline powder, insol. water and alcohol, sl. sol. HOAc, v. sol. CHCl<sub>3</sub>.

**Nitro-glyoxyrrhizin**  $C_{12}H_{10}(NO_2)NO_4$ . Formed by treating a solution of glyoxyrrhizin in HOAc with  $HNO_3$ . Powder.

**GLYOXAL**  $C_2H_2O_2$ , i.e. CHO.CHO. *Oxalic aldehyde*. Mol. w. 58. Formed by the action of nitric acid on alcohol (Debus, *A.* 102, 20; 107, 199; 110, 316; 118, 253), aldehyde or paraldehyde (Lubavin, *B.* 8, 768).

**Preparation**.—1. Obtained from the mother-liquor in the preparation of glyoxylic acid by the slow oxidation of alcohol by  $HNO_3$ ; the liquid is mixed with several times its volume of conc.  $NaHSO_4$  aq. The crystalline compound is subsequently decomposed by dilute  $H_2SO_4$ .—2. Paraldehyde (25 g.) is mixed with water (25 g.);  $HNO_3$  (20 c.c. of S.G. 1.37) is poured in so as to form a lower layer of liquid, and below this again fuming  $HNO_3$  (1 c.c.) is introduced. After a week the liquid is evaporated at 100°, taken up in water, neutralised by  $CaCO_3$ , glycollic and glyoxylic acids p.p.d. by lead subacetate, filtered, freed from excess of lime by oxalic acid, again filtered, and evaporated (De Forcrand, *Bl.* [2] 41, 240).

**Properties**.—Amorphous, slightly deliquescent mass. After drying at 100° it contains 2 aq and is v. e. sol. water, but after drying at 120° it is v. sl. sol. cold water. At 170° it is partially converted into glycollic acid. It is v. e. sol. alcohol and ether. It reduces ammoniacal  $AgNO_3$ , forming a mirror. Water at 150° converts two-thirds of it into glycollic acid.

**Reactions**.—1. A small quantity of very dilute nitric acid oxidises it to glyoxylic acid; a larger quantity of nitric acid forms oxalic acid. 2. Aqueous alkalis convert it into glycollic acid, even in the cold.—3. Cold aqueous KCy forms a black substance.—4. Ammonium cyanate forms glycooll (Lubavin, *J. R.* 1882, 281; *C. J.* 44, 178).—5. Conc. aqueous  $NH_3$  forms, in the cold, glycosine  $C_2H_5N$ , and glyoxaline  $C_2H_5N_2$ .—6. An alcoholic solution of aniline forms  $C_{12}H_{12}N_2$  (Schiff, *B.* 11, 831), a crystalline base, insol. water, sol. alcohol, forming the platinochloride  $B_2H_2PtCl_4$  and the nitro-derivatives  $C_{12}H_{12}(NO_2)_2N_2$  and  $C_{12}H_{12}(NO_2)_4N_2$ .—7. Aniline heated with the compound of glyoxal with  $NaHSO_4$  forms the anilide of phenyl-amido-acetic acid  $NHPh.CH_2.CO.NHPh$  [113°] (Hinsberg, *B.* 21, 110).—8. (α)- and (β)-Naphthylamine heated with the compound of glyoxal with  $NaHSO_4$  form the sodium salt of the sulphate of (α)- and (β)-naphthoxindole  $C_{10}H_7\langle\begin{smallmatrix} NH \\ CH_2 \end{smallmatrix}\rangle CO$  (Hinsberg).—9. Aceto-acetic

oxy-furfuryl-acetic acid and an ether  $C_8H_8O_2$  [139°] which crystallises in plates, v. sol. most menstrua, insol. alkalis, and on saponification gives an acid [75°] (Polonowsky, *A.* 246, 17).—10. Gaseous HCl passed through a mixture of glyoxal and ethylene mercaptan forms

—11. Malonic ether (2 mols.) acted on by glyoxal (1 mol.) and zinc chloride gives rise to di-oxy-butane tetra-carboxylic ether  $(CO_2Et)_2.CH.CH(OH).CH(OH).CH(CO_2Et)_2$  (Polonowsky, *A.* 246, 1).—12. Aceto-acetic ether and conc.  $ZnCl_2$  aq forms di-methyl-furfurane di-carboxylic acid  $O \langle \begin{smallmatrix} C(CH_3.CO_2H):CH \\ CMe=C(CO_2H) \end{smallmatrix} \rangle$ , a compound  $C_8H_8O_4$  [139°], and oily  $O \langle \begin{smallmatrix} C(CHAc.CO_2Et):CH \\ CMe=C(CO_2Et) \end{smallmatrix} \rangle$ .—13. Aqueous di-methyl-urea evaporated with glyoxal and a little HCl forms tetra-methyl-glycoluril

**Combinations**  $C_2H_2O_2(NH_4HSO_4)_2$ ; prisms, v. sol. water, insol. alcohol (De Forcrand, *C. R.* 100, 642).— $C_2H_2O_2(NaHSO_4)_2$  aq; small crystals, v. sol. water, insol. alcohol. — $C_2H_2O_2(KHSO_4)_2$ ; prisms (De Forcrand, *C. R.* 98, 1537).— $C_2H_2O_2Ba(HSO_4)_2$  2 aq; concentrically-grouped masses. S. 85 at 18°.

**Diphenylhydrazide**  $HC(N_2HPh).CH(N_2HPh)$  [170°]. Got by warming glyoxal or its compound with  $NaHSO_4$  with excess of aqueous phenylhydrazinehydrochloride and sodic acetate (Pickel, *A.* 232, 231; Fischer, *B.* 17, 575). Formed also by the action of phenyl-hydrazine on tri-chloro-lactic acid (Pinner, *B.* 17, 2001). Rosettes of slender needles or plates (from alcohol). Nearly insol. water and light petroleum, sol. benzene and chloroform. By warming with alcoholic  $FeCl_3$  it is oxidised to the 'osotetrazone'  $\langle \begin{smallmatrix} CH.N:NPh \\ CH.N:NPh \end{smallmatrix} \rangle$  [152°] which crystallises from alcohol in dark red plates (Von Pechmann, *B.* 21, 2751).

**Salt**.— $BHCl$  [156°]. Saponified by water. **Phenyl-ethyl-hydrazide**  $HC(N_2EtPh).CH(N_2EtPh)$  [149°]. Formed by adding the compound of glyoxal with  $NaHSO_4$  to a dilute solution of phenyl-ethyl-hydrazine in  $HCl$  aq (Elbers, *A.* 227, 340). Crystals (from alcohol); v. sol. benzene and chloroform, m. sol. ether and cold alcohol.

**Oxim**  $C_2H_3N_2O_2$ , i.e.  $HC(NOH).CH(NOH)$ . **Glyoxim**. [178°]. Formed by the action of hydroxylamine on glyoxal (Wittenberg & Meyer, *B.* 16, 505). Formed also by the action of hydroxylamine upon tri-chloro-lactic acid (Pinner, *B.* 17, 2001). Sublimable. Colourless trimetric tables. Sol. hot water, alcohol, and ether. Boiled with aqueous acids it is resolved into its constituents. By heating with acetic anhydride it yields cyanogen (Lach, *B.* 17, 1578). Phenyl-hydrazine added to its alcoholic solution forms an addition-compound  $C_8H_8N_2O_2N_2HPh$  [110°], which crystallises from alcohol in white scales, insol. water (Polonowsky, *B.* 21, 182).— $AgC_2H_3N_2O_2$ ; white powder.

**Di-acetyl derivative**  $C_6H_5(NOAc)_2$ : [120°]; colourless crystals. By further heating with acetic anhydride it yields cyanogen (Lach, B. 17, 1573).

**Reference.**—CHLORO-GLYOXIM.

**Paraglyoxal hydrate**  $C_2H_4O_3$ , i.e.  $(C_2H_4O_2) \cdot H_2O$ . Formed by passing HCl into a solution of glyoxal (1 vol.) in HOAc (5 vols.) (Schiff, G. 4, 16; A. 172, 1). Powder, insol. water, ether, benzene, and chloroform, sl. sol. boiling alcohol. Prolonged boiling with water converts it into glycollic acid. Caustic alkalis also form glycolates. Boiling  $As_2O_3$  forms amorphous insoluble  $C_2H_4AsO_3$ . BzCl gives amorphous  $C_2H_4BzO_3$ .  
**Orthoglyoxal**  $CH(OH)_2CH(OH)_2$ . *Oxalic orthoaldehyde*.

**Ethyl derivative**  $CH(OEt)_2CH(OEt)_2$  (c. 180°). Formed by the action of NaOEt upon di-chloro-acetal  $CHCl_2CH(OEt)_2$  (Pinner, B. 5, 147). Oil. Entirely destroyed by strong acids.

**GLYOXAL-AMYLIN** v. BUTYL-GLYOXALINE.

**GLYOXAL-ISOBUTYLIN** v. PROPYL-GLYOXALINE.

**GLYOXAL-ETHYLIN** v. METHYL-GLYOXALINE.

**GLYOXALINE**  $C_2H_4N_2$ , i.e.  $\begin{array}{c} CH.NH \\ || \\ CH.N \end{array} > CH$

(Japp, C. J. 43, 17) or  $\begin{array}{c} CH.N \\ | \\ CH.N \end{array} > CH_2$ . *Methylene-*

*acetylene-azine*. [89°]. (255°). V.D. 2.35 (calc. 2.26). Formed, together with glycosine, by the action of strong aqueous ammonia on glyoxal (Debus, A. 107, 204; Lubavin, J. R. 7, 254; Wyss, B. 6, 1543; 10, 1305; Wallach, B. 15, 645). Formed also by the simultaneous action of formic aldehyde and  $NH_3$  on glyoxal (Radziszewski, B. 15, 1495).

**Preparation.**—Glyoxal is treated very gradually with ammonia in slight excess, the temperature being kept down. Glycosine then separates as a brown powder, and the filtered solution contains the glyoxaline together with ammonia, chiefly as acetate. This liquid is boiled with milk of lime to expel the ammonia, then evaporated to a syrup, treated with absolute alcohol to separate mineral salts, and filtered; the residue is strongly pressed to separate as much as possible of the liquid; and the whole of this liquid is distilled from a wide-necked retort. After one rectification the glyoxaline is perfectly pure, and solidifies to a radiate, dazzling-white crystalline mass (Wyss).

**Properties.**—Thick nacreous prisms, v. soft, water, alcohol, and ether; is not deliquescent. Has an alkaline reaction. Not attacked by chromic acid. Not affected by reducing agents, by  $As_2O_3$ , by  $AsCl_3$ , or by  $BzCl$ .

**Reactions.**—1.  $KMnO_4$  oxidises it to formic acid and  $CO_2$ .—2.  $EtBr$  forms  $C_6H_5EtN.HBr$  and  $C_6H_5EtN_2.HBr$ .—3. Benzyl chloride forms in like manner  $C_6H_5(C_6H_5)N_2.C_6H_5Cl$  (Wyss).—4. The hydrochloride treated with  $AgNO_3$  forms a nitroso-derivative.—5. *Hydrogen peroxide* forms oxamide (Radziszewski, B. 17, 1289).—6. *Bromine* added to an aqueous solution of glyoxaline forms tri-bromo-glyoxaline  $C_2H_3Br_3N_2$ , which crystallises from water in needles. It is v. sl. sol. cold water, v. sol. alcoh.

hol, sl. sol. ether. It dissolves in alkalis and is reppd. by acids, behaving as an acid. Its silver salt  $C_2AgBrN_2$ , which can be converted by  $Mel$  into  $C_2MeBrN_2$ , which may be reduced by sodium-amalgam to methyl-glyoxaline.

**Salts.**— $B''H_2PtCl_4$ : orange-red prisms (from hot water) (Debus).— $B''H_2PtCl_4$ , aq (Wallach).— $B''H_2ZnCl_4$ : very soluble crystals.— $B''H_2C_2O_4$ : prisms. S. 2.06 at 19°.— $C_2AgH_2N_2$ : white amorphous pp.; insol. cold water.

**References.**—METHYL-, METHYL-ETHYL-, ETHYL-, PROPYL-, BUTYL-, and ISOMYL-GLYOXALINES.

**GLYOXALINES.** These compounds are derivatives of glyoxaline  $\begin{array}{c} CH-NH \\ || \\ CH-N \end{array} > CH$ .

**General modes of formation.**—They are formed by the condensation of compounds containing the dicarbonyl-group  $-CO.CO-$  ( $\alpha$ -diketones and  $\alpha$ -dialdehydes) with aldehydes and ammonia jointly, the reaction taking place according to Equation II. of the general reactions of this class (v. vol. i. p. 465). Thus glyoxal, aldehyde, and ammonia yield methyl-glyoxaline:—

(Radziszewski, B. 15, 2706; Japp, C. J. 1888, 197; v. also under Equation II., vol. i. p. 465).

The aldehyde necessary for the reaction is sometimes furnished by the preliminary hydrolysis of a portion of the dicarbonyl-compound. Thus the reaction discovered by Debus (T. 148, 209), in which glyoxaline itself is obtained by treating glyoxal with ammonia, is supposed to occur in two stages:

(Radziszewski, B. 15, 1495; Japp, B. 15, 2419). In a similar manner lophine (triphenyl-glyoxaline) is obtained from benzil and ammonia, benzoic aldehyde being first formed (v. vol. i. pp. 467-8); and trimethyl-glyoxaline from diacetyl and ammonia (Von Pechmann, B. 21, 1417).

Glyoxal also reacts with ammonia without first undergoing hydrolysis, yielding glycosine (D.), which is a diglyoxaliline. In this case 3 mols. of glyoxal take part in the reaction, one of these exercising the function of the aldehyde (here a dialdehyde) and the other two that of the dicarbonyl-compound in the aldehyde-diketone-ammonia condensations:

Japp & Glemshaw, *C. J.* 1887, 558; cf. also formation of *tetraphenylglycosine*, vol. i. p. 465).

Wallach has shown that chlorinated glyoxalines are formed by the action of phosphorus pentachloride on *s*-dialkylamides (*A.* 184, 33; 214, 278; *B.* 16, 546; *v.* also Japp, *B.* 15, 2418; *C. J.* 1888, 197). In the first stage an imido-chloride is formed: thus *s*-dimethyloxamide would yield

chloride was not isolated in this particular case, but the corresponding diethyl-compound was obtained.) The imido-chloride parts, either spontaneously or on gently heating, with the elements of hydrochloric acid, yielding a chlorinated glyoxaline. Thus with dimethyloximido-chloride:

The mechanism of this reaction is not understood (Wallach, *B.* 16, 546). By heating with hydriodic acid and amorphous phosphorus, the compound is reduced to the corresponding 'oxalmethylene' (tertiary methylglyoxaline). The name 'oxalines' was given to this class of compounds to denote their connection with oxalic acid, before it was recognised that they were derivatives of glyoxaline. The general formula of the 'oxalines' derived from *s*-di-alkylamides of the formula

Another class of glyoxalines are the anhydroses derived from orthodiamines: thus anhydrazetdiaminobenzene (ethenylphenylenediamine)

is obtained by reducing *o*-nitracetanilide with tin and hydrochloric acid:

(Hübner, *A.* 209, 859). The same compounds may be prepared from the orthodiamines by heating them with carboxylic acids: thus *o*-diaminobenzene and acetic acid yield the foregoing anhydrazetdiaminobenzene (Ladenburg, *B.* 8, 677).

Ladenburg (*B.* 11, 590) obtained by the condensation of aldehydes with orthodiamines a class of stable bases to which he gave the

name of 'aldehydines.' Hinsberg (*B.* 19, 2026) has shown that these compounds are tertiary anhydroses. Thus (1, 3, 4)-tolylendiamine and benzaldehyde form benzyl-anhydrosediamidotoluene:

The aldehydines, therefore, also belong to the class of the glyoxalines.

**General properties and reactions.**—Glyoxaline and most of its true homologues are solid compounds; but the derivatives in which the alkyl-group is attached to nitrogen are generally liquid. The glyoxalines are monacid bases, and behave towards alkyl iodides like secondary bases; thus glyoxaline yields with methyl iodide the compound  $\text{C}_6\text{H}_5\text{N(CH}_3\text{)N}_2\text{CH}_3\text{I}$ , which by treatment with moist silver oxide is converted into an ammonium hydroxide; this by distillation yields

The conversion of the secondary glyoxalines into tertiary compounds by the introduction of an alkyl-group lowers the boiling-point: thus glyoxaline boils at 255°, tertiary methyl-glyoxaline at 197°–199°. When the tertiary alkyl-glyoxalines are distilled through a red-hot tube, the alkyl leaves the nitrogen and attaches itself to the 'meso' carbon atom: i.e. the carbon atom which is situated between the two nitrogen atoms. In this way the foregoing tertiary, methylglyoxaline may be converted into *meso*-methyl-

compound (*v. supra*) obtained from glyoxal, aldehyde, and ammonia (Wallach, *B.* 16, 542; Radziszewski, *B.* 45, 2706). By oxidation with hydrogen peroxide, glyoxaline and its *meso*-homologues yield oxamide; whilst the tertiary alkyl-glyoxalines and their *meso*-homologues yield monalkyl oxamides: thus oxalethylene  $\begin{array}{c} \text{CH-N(C}_2\text{H}_5\text{)} \\ \text{CH} \end{array} \text{---} \text{N} \text{---} \text{C.CH}_3$ , gives ethyloxamide (Radziszewski, *B.* 17, 1290).

It has not been found possible to replace the imidic hydrogen in glyoxal and its homologues by acid radicals, and from this Radziszewski (*B.* 15, 1494 and 2706; 16, 492) has argued that glyoxaline contains two tertiary nitrogen atoms,

sults of alkylation and of the oxidation of the alkyl-derivatives prove conclusively that imidic hydrogen is present, and far outweigh this merely negative evidence (Japp, *B.* 15, 2419; 16, 284; Wallach, *B.* 16, 538). Besides, glyoxaline gives off ammonia when heated with aniline hydrochloride, and sulphuretted hydrogen when its aqueous solution is heated with carbon disulphide—reactions which a tertiary base would hardly exhibit (Wallach, *B.* 16, 539).

**Classification.**—The glyoxalines are amidines

in which two hydrogen atoms—one in the amido- and one in the imido-group—have been replaced by the dyad group  $-\text{CR}=\text{CR}-$  so as to convert the complex  $\text{R}'\text{C} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix}$  into

$\text{R}'\text{C} \begin{smallmatrix} \text{NH}-\text{CR}' \\ \text{N}-\text{CR}' \end{smallmatrix}$ , forming a closed-chain compound. Thus glyoxaline itself is formamidine  $\text{CH} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix}$  into which the group  $-\text{CH}=\text{CH}-$  has been introduced. The amidines, like the glyoxalines, are monacid bases.

Glyoxaline is one of the two possible compounds which may be derived from pyrrole as pyridine is derived from benzene—by replacing a  $\text{CH}$ -group by triadic nitrogen:

F. R. J.

GLYOXAL ENANTHYLINE v. HEXYL GLYOXALINE.

GLYOXALIC ACID v. GLYOXYLIC ACID.

GLYOXAL-PROPYLINE v. ETHYLGLYOXALINE.

GLYOXIM v. Di-oxim of GLYOXAL.

GLYOXYLIC ACID  $\text{C}_2\text{H}_2\text{O}_4$  i.e.  $\text{H.CO.CO}_2\text{H}$ . Glyoxalic acid.

**Occurrence.**—In the leaves and unripe fruits of many plants (Brunner, *B.* 19, 595).

**Formation.**—1. By the action of nitric acid upon alcohol, glycol, glyoxal, or glycerin (Debus, *P. M.* [4] 42, 361; *A.* 100, 1; 102, 28; 110, 316; Heintz, *A.* 152, 325).—2. By boiling silver di-bromo-acetate with water (Perkin, *C. J.* 21, 197; 32, 90).—3. By heating di-chloro-acetic ether with water (Fischer, *A. Geuther, J. Z.* 1, 47).—4. By boiling silver di-chloro-acetate with water (Beckurts a. Otto, *B.* 14, 581).—5. By heating silver bromo-glycolate with ether in sealed tubes there is formed an amorphous substance (? glyoxylic anhydride) which is converted by boiling water into glyoxylic acid (Perkin a. Duppa, *C. J.* 21, 197).—6. By heating dry silver di-chloro-acetate at  $80^\circ$  there is formed an oil  $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_4$ , which is split up by water into glyoxylic and di-chloro-acetic acids (Beckurts a. Otto, *B.* 14, 586).

**Preparation.**—1. Di-bromo-acetic acid (1 pt.) is heated with water (10 pts.) for 24 hours at  $135^\circ$  (Grimaux, *Bl.* [2] 26, 483).—2. 220 g. of alcohol of 80 p.c. are poured into a tall narrow flask capable of holding about 1½ lb. of water; 100 g. of water are introduced below the alcohol by means of a funnel having its neck finely drawn out; and below this are poured 200 g. of red fuming nitric acid, so that the three liquids may remain one above the other and mix as little as possible at first. The whole is left for six or eight days, at a temperature of  $20^\circ$ – $22^\circ\text{C}$ ., till the liquids have become completely mixed, and the resulting nitrite of ethyl has volatilised. The residual liquid—containing nitric, acetic and formic acids, compound ethers, glyoxal and other aldehydes, glycollic acid and glyoxylic acid—is evaporated to a syrup over the water-bath in portions of 20 to 30 g. each; the residues, containing oxalic, glycollic, and glyoxylic acids,

together with the less volatile aldehydes, are dissolved in small quantities of water; the united solutions are neutralised with chalk; the neutral liquid is mixed with an equal volume of alcohol; and the resulting pp. of calcium-salts pressed and repeatedly boiled with water. The aqueous extract yields crystals of glyoxylate of calcium, and a further quantity of this salt may be obtained by concentrating the mother-liquor. The subsequent mother-liquors yield a double salt of glycolate and glyoxylate of calcium, and the last contain glycolate of calcium (Debus). 7,500 c.c. alcohol yield 308 g. glyoxylic acid (Böttger, *A.* 198, 207).

**Properties.**—Thick syrup (S.G. 1.3), which crystallises over  $\text{H}_2\text{SO}_4$  in trimetric prisms containing aq. and which may therefore be looked upon as orthoglyoxylic acid  $\text{CH}(\text{OH})_2.\text{CO}_2\text{H}$ . V. sol. water. When strongly heated it gives off acid vapours, leaving a carbonaceous residue. Volatile with steam. Its calcium salt reduces boiling ammoniacal silver nitrate forming a mirror. Glyoxylic acid forms compounds with  $\text{NaHSO}_4$ , with  $\text{H}_2\text{S}$ , and with  $\text{NH}_3$ . An aqueous solution of calcium glyoxylate is ppd. by excess of lime-water, and the pp.  $\text{Ca}(\text{O}_2\text{C})_2$ , is converted by boiling water into a mixture of glycolate and oxalate. When a solution of calcium glyoxylate is mixed with aniline oxalate, and the liquid is filtered from calcium oxalate, a colourless solution is obtained, which, when boiled or even when left to itself for a few hours, deposits a bright orange-coloured precipitate (Perkin a. Duppa). Aniline (75 g.) acts upon syrupy glyoxylic acid (42 g.) forming  $\text{PhN}:\text{CH.CO}_2\text{NPhH}_2$ , and its aniline salt  $\text{PhN}:\text{CH.CO}_2\text{NPhH}_2$ ; the aniline salt is converted by long boiling with water into a red powder  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  (Böttger, *A.* 198, 222). The barium salt  $(\text{PhN}:\text{CH.CO}_2)_2\text{Ba}$  is v. e. sol. water, insol. alcohol. Phenyl-hydrazine solution gives a pp. in an aqueous solution of glyoxylic acid.

**Reactions.**—1. Zinc is dissolved by glyoxylic acid, the acid being reduced to glycollic acid.—2. Nitric acid oxidises it to oxalic acid.—3.  $\text{PBr}_3$  forms di-bromo-acetyl bromide (Perkin a. Duppa, *C. J.* 21, 197).—4.  $\text{PCl}_5$  acting on the potassium salt  $\text{KA}^{\text{aq}}$  forms di-chloro-acetyl chloride,  $\text{KCl}$ , di-chloro-acetic acid, and free glyoxylic acid  $\text{CHO.CO}_2\text{H}$  (Beckurts a. Otto, *B.* 14, 1619).—5. Boiling aqueous  $\text{KOH}$  forms glycollic and oxalic acids (Böttger, *B.* 13, 1932).—6. By treatment with potassium cyanide and boiling the product with baryta there is formed tartronic acid  $\text{CO}_2\text{H.CH}(\text{OH}).\text{CO}_2\text{H}$ .—7. *Tolylene-o-diamine* on boiling with calcium glyoxylate forms a crystalline acid  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N} \\ \text{NH} \end{smallmatrix} \text{C.CO}_2\text{H}$ ; aq. sol. water, v. sol. alcohol, and decomposing at  $160^\circ$  (Hinsberg, *A.* 237, 358).

**Salts.**—With the exception of the ammonium and potassium salts, these might equally well be described as salts of ortho-glyoxylic acid.— $\text{NH}_4\text{A}$ : small prisms, v. sol. water (Perkin; cf. Engel, *C. R.* 98, 928). Its concentrated solution turns yellow when boiled. Gives pps. with  $\text{AgNO}_3$ , with  $\text{Pb}(\text{OAc})_2$ , and with  $\text{CuSO}_4$ .— $\text{KA}$ : ppd. as an oil by adding alcohol to its aqueous solution; so. lifies after a time. Insol. alcohol.— $\text{BaA}$ : 4aq; small white crystals; partly resolved by boiling water into glycolate and oxalate.— $\text{CaA}$ : 2aq;

thin needles of hard prisms. S. 57 at 8°. It does not give off water at 170°, but at 180° it gives off water and CO<sub>2</sub>, leaving glycolate and carbonate.—Ca<sub>2</sub>(C<sub>2</sub>H<sub>2</sub>O<sub>3</sub>)<sub>2</sub>.—CaA', 4aq: gelatinous pp. got by adding alcohol to the aqueous solution.—(CaA')<sub>2</sub>(NH<sub>4</sub>)<sub>2</sub>, 2aq.—(CaA')<sub>2</sub>(NH<sub>4</sub>)<sub>2</sub>: formed by adding ammonia to an aqueous solution of calcium glyoxylate at 50°.—Pb(OH)A'.—Zn(OH)A' aq: white crystalline pp. got by adding a conc. solution of calcium glyoxylate to zinc acetate.—AgA' aq: white crystalline powder; sl. sol. cold water.—(AgA')<sub>2</sub>(NH<sub>4</sub>)<sub>2</sub> (Debus).

**Combinations with bisulphites.**—NaA'NaHSO<sub>3</sub>: formed by adding a conc. solution of NaHSO<sub>3</sub> to one of glyoxylic acid. Crystals, v. sol. water.—(CaA')<sub>2</sub>Ca(SO<sub>3</sub>H)<sub>2</sub>, 10aq: formed by passing SO<sub>2</sub> into water, in which calcium glyoxylate is suspended.—Calcium glyoxylate and glycolate (Ca(C<sub>2</sub>H<sub>2</sub>O<sub>3</sub>)<sub>2</sub>)<sub>2</sub>Ca(C<sub>2</sub>H<sub>2</sub>O<sub>3</sub>)<sub>2</sub>, 4aq.—Calcium glyoxylate and lactate Ca(C<sub>2</sub>H<sub>2</sub>O<sub>3</sub>)<sub>2</sub>Ca(C<sub>2</sub>H<sub>3</sub>O<sub>3</sub>)<sub>2</sub> aq.

**Phenyl-hydrazide** C<sub>6</sub>H<sub>5</sub>NH.N:CH.CO<sub>2</sub>H. Formed as a pp. of fine yellow needles by adding a solution of phenyl-hydrazine hydrochloride to an aqueous solution of glyoxylic acid (Fischer, B. 17, 577). Yellow needles. Decomposes at 137°. Sol. alcohol and hot water.

**Phenylethyl-hydrazide** C<sub>6</sub>H<sub>5</sub>NEt.N:CH.CO<sub>2</sub>H. Ppd. by adding phenylethyl-hydrazine hydrochloride to a dilute solution of calcium glyoxylate acidified by HCl (Elbers, A. 227, 340). White needles, m. sol. hot water, v. sol. alcohol and acetic acid.

**Orthoglyoxylic acid** CH(OH).CO<sub>2</sub>H. This is perhaps the true formula of glyoxylic acid.

**Di-ethyl-derivative** CH(OEt)<sub>2</sub>CO<sub>2</sub>H.

**Formation.**—1. From tetra-chloro-ethylene and NaOEt at 100°–120° (Geuther a. Fischer, J. 1864, 316).—2. By boiling di-chloro-acetic acid (18 pts.) with alcohol (90 pts.), in which sodium (10 pts.) has been dissolved (Schreiber, Z. 1870, 187).

**Properties.**—Unstable oil; split up by boiling with HCl into alcohol and glyoxylic acid.—Ba(C<sub>2</sub>H<sub>3</sub>O<sub>3</sub>)<sub>2</sub>: deliquescent amorphous mass.—AgC<sub>2</sub>H<sub>3</sub>O<sub>3</sub>: m. sol. water.

**Ethyl ether of the di-ethyl derivative** CH(OEt)<sub>2</sub>CO<sub>2</sub>Et. (199° cor.). S.G. 12.994. Formed from CH(OEt)<sub>2</sub>CO<sub>2</sub>Na and EtI at 120° (Schreiber, Z. 1870, 167). Formed also by heating glyoxylic acid with alcohol at 120° (Perkin, B. 8, 188). Obtained by passing HCl into a solution of HCO<sub>2</sub> in dry alcohol (Pinner a. Klein, B. 11, 1475).

**Isobutyl ether of the di-isobutyl derivative** CH(OC<sub>4</sub>H<sub>9</sub>)<sub>2</sub>CO<sub>2</sub>C<sub>4</sub>H<sub>9</sub>. (251°). Formed by passing HCl into a solution of dry HCO<sub>2</sub> in isobutyl alcohol (P. a. K.). Oil. After saponification it gives the salt CH(OC<sub>4</sub>H<sub>9</sub>)<sub>2</sub>CO<sub>2</sub>Ag, which crystallises in small needles, sl. sol. cold water.

**Amide of the di-ethyl derivative** CH(OEt)<sub>2</sub>CONH<sub>2</sub>. [77°]. (Schreiber, Z. 1870, 168); (82°) (Pinner a. Klein, B. 11, 1477). From CH(OEt)<sub>2</sub>CO<sub>2</sub>Et and cold alcoholic NH<sub>3</sub>. Tables or needles (by sublimation). V. sol. water and alcohol.

**Amide of the di-isobutyl derivative** CH(OC<sub>4</sub>H<sub>9</sub>)<sub>2</sub>CONH<sub>2</sub>. [s. 44°]. Crystalline (P. a. K.).

**Reference.**—CHLORO-GLYOXYLIC ETHER.

**GLYOXYLYL CYANIDE** CHO.CO.CN.

**Phenyl-hydrazide** CHO.C(N<sub>2</sub>HPh).CN. [161°]. Formed by the action of a concentrated solution of hydrochloric acid upon the di-oxim of the phenyl-hydrazide of mesoxalic aldehyde CH(NO<sub>2</sub>).C(N<sub>2</sub>HPh).CH(NO<sub>2</sub>) (Von Pechmann a. Wehsarg, B. 21, 3000). Sulphur-yellow needles, insol. water, sol. other solvents. Decomposed on melting. Conc. H<sub>2</sub>SO<sub>4</sub> forms a yellow solution not affected by FeCl<sub>3</sub>. Boiling HIAq liberates aniline. When its dilute alkaline solution is poured into a neutral solution of diazobenzene chloride there is formed C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O(N<sub>2</sub>Ph) [163°] which crystallises from alcohol in brown plates, insol. alkalis.

**Oxim of the phenyl-hydrazide**

CH(NO<sub>2</sub>).C(N<sub>2</sub>HPh).CN. [240°]. Formed by treating the preceding with hydroxylamine hydrochloride in alcoholic solution. Lemon-yellow difficultly soluble needles, decomposed by fusion. Its solution in H<sub>2</sub>SO<sub>4</sub> is not effected by FeCl<sub>3</sub>.

**Di-phenyl hydrazide**

CH(N<sub>2</sub>HPh).C(N<sub>2</sub>HPh).CN. [161°]. Formed by the action of phenyl-hydrazine on a hot alcoholic solution of the monophenylhydrazide CHO.C(N<sub>2</sub>HPh).CN (Von Pechmann a. Wehsarg, B. 21, 3000). Orange-red needles, decomposed on fusion; sol. alcohol and HOAc, sl. sol. most other solvents. The solution in H<sub>2</sub>SO<sub>4</sub> is not affected by FeCl<sub>3</sub>, FeCl<sub>4</sub> or K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, acting on its solution in dilute HOAc forms the 'osotetrazone' <CH.N.NPh>, which crystallises in bronzed hair-like needles, melting, with decomposition, at 187°.

The corresponding acid

CH(N<sub>2</sub>HPh).C(N<sub>2</sub>HPh).CO<sub>2</sub>H [203°] is formed by treating di-bromo-pyruvic acid with phenyl hydrazine (Nastvogel, A. 248, 85). *p*-Tolyl hydrazine and (α)-naphthyl hydrazine form similar acids, melting at 188° and 196° respectively.

**Phenyl-methyl-hydrazide**

CHO.C(N<sub>2</sub>MePh).CN. [114°]. Prepared from CH(NO<sub>2</sub>).C(N<sub>2</sub>MePh).CH(NO<sub>2</sub>) by treating its solution in acetone with conc. HClAq. Converted by phenyl-hydrazine in acetic acid solution into CH(N<sub>2</sub>HPh).C(N<sub>2</sub>MePh).CN [181°], which forms yellow plates. Aniline produces the compound CH(NPh).C(N<sub>2</sub>MePh).CN, which crystallises from alcohol in slender yellow needles [151°].

**Oxim of the phenyl-methyl-hydrazide** CH(NO<sub>2</sub>).C(N<sub>2</sub>MePh).CN. [178°]. Formed from the preceding and hydroxylamine. Yellow needles. Boiling acetic anhydride forms CH(NOAc).C(N<sub>2</sub>MePh).CN, which crystallises from alcohol in yellow needles [122°].

**GLYOXYLYL UREA** C<sub>2</sub>H<sub>2</sub>N<sub>2</sub>O<sub>3</sub>, i.e.

NH<sub>2</sub>.CO.NH.CO.CHO. The potassium salt is formed with evolution of CO<sub>2</sub>, on adding acetic acid to a solution of the potassium salt of oxonic acid C<sub>2</sub>H<sub>2</sub>N<sub>2</sub>O<sub>4</sub> (Medicus, A. 175, 280; B. 9, 1162; 10, 544). Thick shining needles, sl. sol. cold, v. sol. hot, water.—KA': crystalline powder.—AgA': amorphous powder.

**Isomeride v. ALLANTURIC ACID.**

**GNOSCOPIKE** C<sub>2</sub>H<sub>2</sub>N<sub>2</sub>O<sub>3</sub>. [288°]. S. (cold alcohol) 07. An alkaloid obtained from the mother-liquors in the purification of narcotine

(T. a. H. Smith, *Ph.* [3] 9, 82). Sol. chloroform and  $\text{CS}_2$ , sl. sol. benzene. Insol. aqueous or alcoholic NaOH. Dissolves in acids. The solution in conc.  $\text{H}_2\text{SO}_4$  is yellow, turned crimson by a trace of  $\text{KNO}_3$ . A solution of the hydrochloride gives a buff-coloured pp. with platinum chloride.

**GOA POWDER** v. CHRYSAOBIN, p. 173.

**GOLD.** Au (*Aurum*). At. w. 196.85 (Thorpe a. Laurie, *C. J.* 51, 565, 866). At. w. 196.64 (Krüss, *B.* 20, 205, 2366). Mol. w. unknown. [1045°] (Violle, *C. R.* 92, 866); [1240°] (Riemsdyck, *C. N.* 20, 23; for other determinations v. Carnelley's *Melting and Boiling-point Tables*). S.G.  $\frac{17.5}{7.8}$  19.3 to 19.33 (G. Rose, *P.* 73, 1). S.H. 0°-100° .0316 (Violle, *C. R.* 69, 702); 12°-98° .03244 (Regnault, *A. Ch.* [2] 73, 1). C.E. at 40° .00001443 (Fizeau, *C. R.* 68, 1125); 0° to 100° .0000147 (Matthiessen, *Pr.* 15, 220). T.C. 53.2 (Ag = 100) (Wiedmann a. Franz, *P. M.* [4] 7, 33). E.C. at 0° = 43.84 to 44.62 (Hg at 0° = 1) (Matthiessen a. Von Bose, *T.* 152, 1). For description of emission-spectrum v. de Boisbaudran's *Spectres Lumineux*.

Gold has been known and used from prehistoric times. The names by which the metal is known in different languages generally express the property of brightness. The method of separating gold by amalgamating it with mercury is fully described by Pliny.

**Occurrence.**—Gold is found native, generally more or less alloyed with Ag. It occurs in the crystalline, the compact metamorphic, the trachytic, and trap, rocks, and in alluvial soils. The greatest quantity is obtained from alluvial deposits formed by the disintegration of ancient auriferous strata. Gold is most abundant in Europe in Hungary and Transylvania; but it occurs in small quantities in very many primitive mountains or in the sands of rivers issuing from such mountains, e.g. in the southern slopes of the Alps, in North Wales, in the Scottish Highlands, and in the Ural mountains. It is also found in fair quantities in Brazil and Chili, and other parts of S. America; abundantly in California, and parts of Australia, and in British Columbia. The purest specimens of native gold contain about 99 p.c. Au. The Californian gold averages from 87.5 to 88.5 p.c., and the Australian from 96 to 96.6 p.c. Au.

**Extraction of Gold.**—(1) By washing away the earthy particles with water. This is effected on a large scale in California by means of a head of water rushing through a pipe with a narrow nozzle. Sometimes the sands of an auriferous stream are washed in a wooden *cradle*, which is rocked by hand. (2) By amalgamation. The richer gold-containing rocks are crushed and mixed with mercury, whereby an amalgam of Au and Hg is formed; this amalgam is separated from the earthy matter and heated in specially constructed iron retorts; the gold remains and the Hg is recovered. Poorer ores are washed before amalgamation. (3) By smelting. Ores which contain small quantities of Au mixed with Cu and Pb, and sulphides, are sometimes roasted, and then mixed with quartz and smelted; the mass is powdered and treated with dilute  $\text{H}_2\text{SO}_4$ ; the residue is mixed with fresh quantities of ore, and the treatment is repeated; when a fair

quantity of Au has accumulated in the residu it is boiled with conc.  $\text{H}_2\text{SO}_4$  to dissolve Ag, Cu &c., and the insoluble matter is subjected to a process of *parting*. (4) By wet processes. The principal process is that based on converting Au into soluble  $\text{AuCl}_3$  by treatment with Cl. The ore is thoroughly roasted to remove S, As and Sb; the moistened residue is then treated with Cl which must be free from HCl; on addition of warm water, the  $\text{AuCl}_3$  dissolves; the Au is pptd. generally by ferrous sulphate. If whatever way the Au has been separated it is usually still alloyed with Ag; this is separated by *parting*. Sufficient Ag is added to ensure the presence of 5 parts Ag to 2 parts Au; the alloy is granulated and treated with pure nitric acid in which the Ag dissolves, while the Au remains insoluble. Or the alloy, which should contain from 19 to 25 p.c. Au, is treated with hot conc.  $\text{H}_2\text{SO}_4$ ; Ag dissolves and Au is insoluble. The treatment with  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  is repeated; the Au is washed and melted with borax and nitre. For details of these and other processes of gold extraction v. **DICTIONARY OF TECHNICAL CHEMISTRY**.

**Preparation.**—Au may be obtained from any alloy with Ag in which it is present by treating with a mixture of 2 measures of conc.  $\text{HClAq}$  and 1 of conc.  $\text{HNO}_3$ , filtering, evaporating at 100° until acid vapours are no longer evolved, dissolving the residue in warm water acidulated with HCl, filtering, and ppg. Au by addition of  $\text{FeSO}_4\text{Aq}$ . Or an alloy of Ag and Au, or of Ag, Cu, and Au, containing not more than 20 p.c. Au, may be granulated, heated with  $\frac{2}{3}$  times its weight of  $\text{H}_2\text{SO}_4\text{Aq}$  S.G. 1.815 in a Pt vessel as long as  $\text{SO}_2$  is evolved, boiled with a little more  $\text{H}_2\text{SO}_4\text{Aq}$  S.G. 1.65, and allowed to settle; the liquid is then poured off and the treatment with  $\text{H}_2\text{SO}_4$  S.G. 1.815 is repeated once or twice; finally the residual Au is washed and dried. Krüss (*A.* 238, 30) prepared pure Au, for his determination of the atomic weight, by dissolving the purest commercial Au in *aqua regia*, evaporating to dryness at 100° with HCl, dissolving in water, diluting largely, and filtering; he then pptd. the Au (1) by  $\text{SO}_2$ , followed by washing with  $\text{HClAq}$  and water, drying at 180°, digesting with conc.  $\text{H}_2\text{SO}_4$  in a Pt dish, washing with hot water, drying, fusing (in Pt) with  $\text{KHSO}_4$  (to remove Pd), then fusing with  $\text{KNO}_3$  (to remove Ir), redissolving in *aqua regia*, and reppg. by  $\text{SO}_2$ . By method (2) the Au was pptd. from the dilute  $\text{AuCl}_3$  solution by oxalic acid; in method (3) the pptant. used was  $\text{FeCl}_3$ . In each case the Au was washed, dissolved in *aqua regia*, and reppd. by  $\text{SO}_2$ , again washed, and redissolved in *aqua regia*, and finally pptd. by oxalic acid. Thorpe a. Laurie (*C. J.* 51, 570) prepared pure Au, from old assay cornets, by dissolving in *aqua regia*, evaporating to remove excess of nitric acid, diluting with much water, allowing to settle for several weeks, pouring off from traces of  $\text{AgCl}$ , ppg. by  $\text{SO}_2$ , and boiling the pp. with water till every trace of Cl was removed.

• **Properties.**—Au is the only metal of a yellow colour; in thin sheets it appears greenish by transmitted light. Au pptd. from solution by  $\text{SO}_2\text{Aq}$  or  $\text{FeSO}_4\text{Aq}$  appears as a lustreless, brown-yellow to reddish, powder. Au crystallises in regular forms chiefly octahedra and dodecahedra.

Au is softer than Ag but harder than Sn. When pure, Au is the most malleable of all metals, sheets .0001 mm. thick have been obtained. The ductility of Au is nearly limitless; a grain of Au has been drawn into a wire 500 ft. long. Au is not oxidised by heating in air; it is volatilised and perhaps partially oxidised when a strong electric current is passed through thin leaves or wires. Insoluble in  $\text{HNO}_3$ , conc.  $\text{HClAq}$ , or  $\text{H}_2\text{SO}_4$ ; dissolved by *aqua regia*. Cl and Br combine direct with Au forming  $\text{AuCl}_3$  and  $\text{AuBr}_3$ , respectively; the metal also combines directly with P; and it forms alloys with several metals (*v. infra*, ALLOYS). Compounds of Au are generally easily decomposed by heat, yielding Au. *Purple of Cassius* is probably a mixture of  $\text{SnO}_2$  with Au (*v. Tin*, oxides or).

Gold is distinctly and decidedly metallic in its physical properties; but in many of its chemical relations it belongs to the non-metals. The composition of the aurous compounds  $\text{Au}_2\text{O}$ ,  $\text{Au}_2\text{S}$ ,  $\text{AuCl}$ , &c., marks the resemblance between Au and the alkali metals; the solubility in water of  $\text{Au}_2\text{S}$  and  $\text{Au}_2\text{O}$  emphasises this resemblance. The marked instability of the salts of Au, the acidic character of the hydroxide  $\text{AuO}_2\text{H}_3$ , of the sulphides  $\text{Au}_2\text{S}$  and  $\text{AuS}$ , and the existence of the acids  $\text{HAuCl}_4$  and  $\text{HAuBr}_4$ , mark the analogy between Au and the non-metals. In the classification based on the periodic law, Au is placed both in Group I, which contains the alkali metals, and in Group VIII, which contains the metals Fe Ni Co and also the Pt metals. Au is the first member of series 11, in which it is followed by Hg, Tl, Pb, and Bi; these four elements are decidedly metallic, but both Pb and Tl form salts in which they play the part of negative elements. (For a further discussion of the chemical relations of Au *v. COPPER GROUP OF ELEMENTS*, p. 250.)

The atomic weight of Au has been determined very carefully by Thorpe & Laurie, from (1) the ratio  $\text{Au:KBr}$ , and (2) the ratio  $\text{Au:AgBr}$ ; the salt used was  $\text{KAuBr}_4$  (*C. J.* 51, 565, 866). Krüss (*B.* 20, 205, 2866) has also determined the at. w. from analyses of  $\text{KAuBr}_4$ , and also of  $\text{AuCl}_3$ . (For an account of older determinations *v. paper of Thorpe & Laurie*.)

*Allotropic form of Gold.*—According to Thomsen (*Th.* 3, 398) the Au *ppd.* by  $\text{SO}_2\text{Aq}$  from solutions of  $\text{AuBr}_3$  differs from that *ppd.* from  $\text{AuCl}_3\text{Aq}$ ; the thermal measurements of the two reduction-procedures show, according to Thomsen, that Au *ppd.* from  $\text{AuBr}_3$  possesses energy equal to 3,210 gram-units of heat, per 197 grams of gold, more than the Au *ppd.* from  $\text{AuCl}_3$ .

*Gold, alloys of.* Gold alloys with most metals. The alloys which are of most technical importance are those with copper and silver. Pure Au is too soft for making jewellery, watches, coins, &c.; alloying it with Cu increases the hardness, and produces a redder colour than that of pure Au. Alloying with Ag gives a lighter colour. Alloys of Au with Cu and Ag are more fusible than pure Au. The standard coinage of the United Kingdom is 11 Au to 1 Cu. Au forms amalgams with Hg. By dissolving 1 pt. Au in about 1,000 pts. Hg, pressing through chamois leather, and treating the residue with  $\text{HNO}_3\text{Aq}$ , a solid amalgam approximating to the composition  $\text{Au}_2\text{Hg}$  is said to be obtained

(Henry, *P. M.* (4) 9, 468). An amalgam, approximately  $\text{Au}_2\text{Hg}_3$ , is found native in California. Another amalgam, approximately  $\text{Ag}_2\text{Au}_3\text{Hg}_{10}$ , is found in New Granada. The pasty amalgam of 2 pts. Au with 1 pt. Hg is sometimes used for gilding articles of copper and bronze. The surface of the article is cleaned thoroughly by heating and immersing in dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , it is then amalgamated by rubbing with  $\text{Hg}(\text{NO}_3)_2\text{Aq}$ , and then pressed on the pasty amalgam of Au; the Hg is then driven off by heat, and the surface is polished. Copper may also be gilded by immersion in boiling  $\text{AuCl}_3\text{Aq}$  to which an alkaline carbonate has been added. The process of gilding generally consists in depositing Au from solution of the cyanide in  $\text{KCNaAq}$  by an electric current, the object to be gilded being made the negative pole, while the positive consists of a bar of gold (*v. DICTIONARY OF TECHNICAL CHEMISTRY*).

Gold bromides. Aurous bromide  $\text{AuBr}$ , and auric bromide  $\text{AuBr}_3$ , have been isolated, and, according to Thomsen, a third bromide  $\text{AuBr}_2$  also exists; as none of the bromides has been gasified, the above formulæ may or may not be molecular. Thomsen gives the following thermal data (*Th.* 3, 412)  $[\text{Au}, \text{Br}] = -80$ ;  $[\text{Au}, \text{Br}^2] = 8,850$ ;  $[\text{Au}, \text{Br}^3, \text{Ag}] = 5,090$ ;  $[\text{AuBr}^3, \text{Ag}] = -3,760$ ;  $[\text{AuBr}^3\text{Aq}, 3\text{HClAq}] = 4,280$ .  $\text{AuBr}_3$  combines with HBr to form  $\text{HAuBr}_4$  (*v. infra*).

Aurous bromide  $\text{AuBr}$  (or  $\text{Au}_2\text{Br}_2$ ).  $\text{HAuBr}_4 \cdot 5\text{H}_2\text{O}$  (*v. infra*) is placed in a porcelain basin, the bottom, but not the sides, of which is gently heated; the salt melts and then evolves  $\text{H}_2\text{O}$  and HBr; the dish is then kept in a drying oven at  $115^\circ$  until the colour is yellowish-grey (Thomsen, *Th.* 3, 390).  $\text{AuBr}$  is described by Thomsen as a greyish-yellow body with a talc-like appearance, unchanged in air and insoluble in water; decomposed somewhat above  $115^\circ$  into Br and Au; reacts with  $\text{HBrAq}$  to form  $\text{HAuBr}_4$  and Au.

Auro-auric bromide  $\text{AuBr}_2$  (or  $\text{AuBr} \cdot \text{AuBr}_3$ ). According to Thomsen (*Th.* 3, 386), this compound is produced by treating Au which has been reduced by  $\text{SO}_2\text{Aq}$  and dried at  $170^\circ$  with excess of Br, removing the excess of Br by tilting the vessel, powdering the residue, and again treating with a little Br. Thomsen describes  $\text{AuBr}_2$  as a compact, almost black, non-deliquescent, mass; at c.  $115^\circ$  it is decomposed to  $\text{AuBr}$  and Br; it dissolves slowly in water to form  $\text{AuBr}$  and  $\text{AuBr}_3$ ; it is decomposed rapidly by acids and also by anhydrous ether into  $\text{AuBr}_3$ , which dissolves, and a residue, probably  $\text{AuBr}$ , which slowly decomposes to  $\text{AuBr}$  and Au. According to Krüss & Schmidt (*B.* 20, 2634)  $\text{AuBr}_2$  does not exist.

Auric bromide  $\text{AuBr}_3$ . *Ppd.* Au is dissolved in  $\text{BrAq}$ , or better in  $\text{HBrAq}$  containing  $\text{HNO}_3$ , and the solution is evaporated at a low temperature. Thomsen (*Th.* 3, 387) recommends to treat  $\text{AuBr}_3$  with anhydrous ether, which is kept cold by the passage through it of a current of air, and then to evaporate the conc. solution thus obtained by sucking a rapid current of air through it (if temperature is not kept low, reduction of  $\text{AuBr}_3$  takes place), to allow the residue to stand over lime until dry, then to powder and dry at  $70^\circ$ .  $\text{AuBr}_3$  is a dark-brown, non-deliquescent, powder; soluble in water and ether; the solu-

uous when conc. are nearly black.  $\text{AuBr}_3\text{Aq}$  is partially reduced by boiling;  $\text{SO}_2\text{Aq}$  forms  $\text{AuBr}$  and then  $\text{Au}$ .  $\text{AuBr}_3$  combines with  $\text{HBr}$  to form  $\text{HAuBr}_4$  (v. *infra*).

**AURO-BROMHYDRIC ACID**  $\text{HAuBr}_3 \cdot 5\text{H}_2\text{O}$  (*Aurobromic acid*, *Bromo-auric acid*, *Hydrogen bromoaurate*). Finely divided  $\text{Au}$  is treated with excess of  $\text{Br}$ ; when the reaction is completed,  $\text{HBrAq}$  S.G. 1.38 is added in the proportion of 100 g. to every 100 g.  $\text{Au}$  used, and then enough  $\text{Br}$  is added to dissolve completely all the  $\text{Au}$ ; the liquid is poured into a porcelain dish which is allowed to stand in a cool place. Large, dark, vermilion-red crystals soon separate; after an hour or so the mother liquor is poured off, and the crystals are dried at a temperature not exceeding  $20^\circ$ . The crystals melt at  $27^\circ$ ; they are unchanged in ordinary air.  $\text{HAuBr}_3\text{Aq}$  is reduced to  $\text{Au}$  by  $\text{SO}_2\text{Aq}$  (Th. 3, 383). Thomsen (Th. 3, 411) gives the thermal data:  $[\text{AuBr}_3\text{Aq}, \text{HBrAq}] = 7,700$ ;  $[\text{AuBr}_3, \text{HBrAq}] = 3,880$ ;  $[\text{AuBr}_3, \text{HBr}, 5\text{H}_2\text{O}] = 35,280$ ;  $[\text{Au}, \text{Br}_3, \text{HBrAq}] = 12,790$ ;  $[\text{HAuBr}_3\text{Aq}, 4\text{HClAq}] = -510$ ;  $[3\text{AuBr}_3, \text{HBrAq}] = 3,650$ ;  $[\text{AuBr}_3\text{Aq}, 2\text{SO}_2\text{Aq}] = 61,790$ ;  $[\text{HAuBr}_3 \cdot 5\text{H}_2\text{O}, \text{Au}] = -11,400$ .

**Aurobromate of potassium**  $\text{KAuBr}_3$ , *Potassium bromoaurate*. Monoclinic crystals;  $a:b:c = 79688:1:361$ ;  $\beta = 85^\circ 34' 2''$  (Schottländer, A. 240, 346). Prepared by dissolving a mixture of finely-divided  $\text{Au}$  and  $\text{KBr}$ , in the ratio  $\text{Au}:\text{KBr}$ , in excess of  $\text{Br}$  with addition of a considerable quantity of water, evaporating, and crystallising from water (Thorpe a. Laurie, C. J. 51, 571). The salt is decomposed by heat to  $\text{Au}$  and  $\text{KBr}$ . According to Krüss (B. 20, 2365)  $\text{KAuBr}_3$  cannot be obtained perfectly free from traces of  $\text{Au}$ ; but this is denied by Thorpe a. Laurie (C. J. 51, 866). The salt in solution is very easily partially reduced.

**Gold chlorides.** Two chlorides  $\text{AuCl}$  and  $\text{AuCl}_3$  certainly exist; Thomsen says that a third chloride,  $\text{AuCl}_2$ , is also produced by the reaction between  $\text{Au}$  and  $\text{Cl}$ ; this is denied by Krüss, but re-asserted by Thomsen. The formulae  $\text{AuCl}$ ,  $\text{AuCl}_2$ , and  $\text{AuCl}_3$  are the simplest that can be given; but as the compounds have not been gasified these formulae are not necessarily molecular.

**Aurous chloride**  $\text{AuCl}$ . Best prepared according to Thomsen (Th. 3, 386) by heating  $\text{AuCl}_3$  to  $185^\circ$ . Yellowish-white powder; insol. water, but decomposed by water, quickly on heating, to  $\text{AuCl}_3\text{Aq}$  and  $\text{Au}$ .  $[\text{Au}, \text{Cl}] = 5,810$ ;  $3\text{AuCl}, \text{HClAq} = 4,980$  (Th. 3, 411).

**AURO-AURIC CHLORIDE**  $\text{AuCl}_2$  (or  $\text{AuCl} \cdot \text{AuCl}_3$ ). Thomsen (Th. 3, 383) describes this compound as a hard, dark red, very hygroscopic, solid; decomposed by water to  $\text{AuCl}$  and  $\text{AuCl}_3\text{Aq}$ ; decomposes at c.  $250^\circ$  giving some  $\text{AuCl}$ ; prepared by leading dry  $\text{Cl}$  over  $\text{Au}$  p.p.d. by  $\text{SO}_2\text{Aq}$  from  $\text{AuCl}_3\text{Aq}$ , the reaction being started by gentle heating and then allowed to proceed until the  $\text{Au}$  is changed to  $\text{AuCl}_3$  (Th. 3, 383; v. also Thomsen, J. pr. [2] 37, 105). Krüss a. Schmidt B. 20, 2634; and also J. pr. [2] 38, 77 assert that the products of the action of  $\text{Cl}$  on  $\text{Au}$  are mixture of  $\text{Au}$  and  $\text{AuCl}_3$ , and that no  $\text{AuCl}_2$  is produced.

Krüss (B. 20, 211) says that when finely-divided  $\text{Au}$  is heated in dry  $\text{Cl}$  to  $140^\circ$  aurous chloride is produced; at  $180^\circ$ – $190^\circ$  this

is decomposed with formation of  $\text{AuCl}$  and a little  $\text{AuCl}_3$ ; at  $220^\circ$ – $230^\circ$  a little more  $\text{AuCl}_3$  is obtained and the  $\text{AuCl}$  decomposes to  $\text{Au}$  and  $\text{Cl}$ , and that the  $\text{Au}$  thus produced remains unchanged in the  $\text{Cl}$ ; on cooling these reactions are reversed. But in a subsequent memoir Krüss a. Schmidt say that the only products of the reaction of  $\text{Au}$  with  $\text{Cl}$  are  $\text{AuCl}$  and  $\text{AuCl}_3$ , and finally  $\text{AuCl}$ , and  $\text{Au}$ .

**AURIC CHLORIDE**  $\text{AuCl}_3$ . Formed by dissolving  $\text{Au}$  in *aqua regia*, evaporating, and crystallising, and drying on a porous tile over conc.  $\text{H}_2\text{SO}_4$  for several days. A purer product is obtained by evaporating the solution in *aqua regia* to dryness, heating the residue to  $185^\circ$  so long as  $\text{Cl}$  is evolved, decomposing the  $\text{AuCl}$  thus formed by a very little hot water, allowing to settle, decanting from  $\text{Au}$ , and evaporating to dryness the conc.  $\text{AuCl}_3\text{Aq}$  thus obtained over a flame arranged so that the bottom and not the sides of the vessel is kept hot; when the residue is heated to  $150^\circ$  pure  $\text{AuCl}_3$  is obtained. Thomsen (Th. 3, 384) recommends to treat  $\text{AuCl}_3$  instead of  $\text{AuCl}$  with water in the manner directed. If conc.  $\text{AuCl}_3\text{Aq}$  is evaporated to the crystallising point, and then allowed to stand in dry air, large orange crystals of the hydrate  $\text{AuCl}_3 \cdot 2\text{H}_2\text{O}$  separate; these are dehydrated by standing on a porous tile over conc.  $\text{H}_2\text{SO}_4$  for some days (Th. 3, 386).  $\text{AuCl}_3$  is also formed by heating finely-divided  $\text{Au}$  in  $\text{Cl}$  (v. *supra*). Lindet (C. R. 101, 1492) recommends to heat  $\text{Au}$  in  $\text{Cl}$  in presence of  $\text{AsCl}_3$ ,  $\text{SiCl}_4$ ,  $\text{SbCl}_3$ ,  $\text{SnCl}_4$ , or  $\text{TiCl}_4$ ;  $\text{AuCl}_3$  is formed and dissolves in the other chloride, but separates in crystals on cooling.

Auric chloride crystallises in large red-brown leaflets; it is very deliquescent, and dissolves in water with production of heat.  $\text{AuCl}_3\text{Aq}$  is easily reduced;  $\text{Au}$  is p.p.d. by  $\text{P}$ , many metals,  $\text{FeSO}_4$ ,  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{As}_2\text{O}_3$ ,  $\text{Sb}_2\text{O}_3$ , and by organic matter; reduction also occurs by the action of light (v. Fousserau, C. R. 103, 248);  $\text{AuCl}_3\text{Aq}$  is not reduced by pure  $\text{NaOH}$ , but if organic matter is present reduction occurs (Krüss, A. 237, 274).  $\text{AuCl}_3$  dissolves in hot  $\text{AsCl}_3$ ,  $\text{SiCl}_4$ ,  $\text{SbCl}_3$ ,  $\text{SnCl}_4$ , and  $\text{TiCl}_4$ , but separates again on cooling. When  $\text{Au}$  is heated with  $\text{S}_2\text{Cl}_2$  the compound  $\text{AuCl}_2 \cdot \text{S}_2\text{Cl}_2$  is formed; and when  $\text{Au}$  is heated with  $\text{SeCl}_4$  dissolved in molten  $\text{AsCl}_3$ , and  $\text{Cl}$  is passed in, the compound  $\text{AuCl}_2 \cdot \text{SeCl}_4$  is produced (Lindet, C. R. 101, 1492).  $\text{AuCl}_3$  combines with  $\text{HCl}$  to form  $\text{HAuCl}_4$  (v. *infra*).  $\text{HBr}$  reacts with  $\text{AuCl}_3$  to form  $\text{HAuCl}_4$ ,  $\text{HAuBr}_4$ , and  $\text{HCl}$  (Th. 3, 410). Thomsen (Th. 3, 411) gives the thermal data:  $[\text{Au}, \text{Cl}_2] = 22,820$ ;  $[\text{AuCl}_3, \text{Aq}] = 4,450$ ;  $[\text{Au}, \text{Cl}_2, \text{Aq}] = 27,270$ ;  $[\text{AuCl}_3 \cdot 2\text{H}_2\text{O}, \text{Aq}] = -1,690$ ;  $[\text{AuCl}_3\text{Aq}, 4\text{HBrAq}] = 15,210$ .

**AURO-CHLORHYDRIC ACID**  $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$  (*Aurochloric acid*, *Chloro-auric acid*, *Hydrogen chloroaurate*). Long, yellow needles, formed by dissolving  $\text{Au}$  in *aqua regia*, adding a large excess of  $\text{HCl}$ , evaporating to a syrup, and allowing to crystallise. Also by dissolving  $\text{AuCl}_3\text{Aq}$  in  $\text{HClAq}$  and evaporating; in dry air  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  is formed (Th. 3, 407).  $\text{HAuCl}_4$  is also formed, along with  $\text{HAuBr}_4$  and  $\text{HCl}$ , when excess of  $\text{HBrAq}$  is added to  $\text{AuCl}_3\text{Aq}$  (Th. 3, 410).  $[\text{AuCl}_3\text{Aq}, \text{HClAq}] = 4,580$ ;  $[\text{Au}, \text{Cl}_2, \text{HClAq}] = 81,800$ ;  $[\text{AuCl}_3, \text{HCl}, 4\text{H}_2\text{O}] = 82,180$ ;  $[\text{AuCl}_3\text{Aq}, 4\text{HBrAq}] = 15,210$ ;

$[\text{HAuCl}^{\text{I}}\text{Aq}, 4\text{HBrAq}] = 13,800$ ;  
 $[\text{HAuCl}^{\text{I}}\text{Aq}, 4\text{H}^{\text{I}}\text{O}, \text{Aq}] = -5,880$ ;  $[\text{HAuCl}^{\text{I}}\text{Aq}, 8\text{H}^{\text{I}}\text{O}, \text{Aq}]$   
 $= -8,550$ .

**Ammonium auro-chlorate**,  $(\text{NH}_4)_2\text{AuCl}_6$  (**Ammonium chloro-aurate**). By dissolving  $\text{NH}_4\text{Cl}$  in  $\text{AuCl}_3\text{Aq}$  strongly acidified with  $\text{HCl}$ , and evaporating, monoclinic yellow tablets are obtained, having the composition  $4\text{NH}_4\text{AuCl}_6 \cdot 5\text{H}_2\text{O}$ ; if these are dissolved in water and re-crystallised rhombic plates are formed  $2\text{NH}_4\text{AuCl}_6 \cdot 5\text{H}_2\text{O}$ . Both salts are dehydrated at  $100^\circ$ .

**Potassium auro-chlorate** or **chloro-aurate**,  $\text{KAuCl}_4$ . Formed similarly to the  $\text{NH}_4$  salt; crystallises in yellow needles,  $2\text{KAuCl}_4 \cdot \text{H}_2\text{O}$ ; the crystals effloresce in the air; when heated they melt with evolution of  $\text{Cl}$ , and the liquid solidifies to  $\text{KAuCl}_4$ .

**Sodium auro-chlorate** or **chloro-aurate**,  $\text{NaAuCl}_4 \cdot 2\text{H}_2\text{O}$ . Formed similarly to the  $\text{NH}_4$  salt.

Aurochlorates of Ba, Cd, Ca, Co, Mg, Mn, Ni, Sr, and Zn have been obtained by Von Bonsdorff (P. 17, 261; 33, 64).

Gold cyanides; and double cyanides, also auricyanides, v. pp. 331-2.

Gold, fulminating, v. AURIC OXIDE, *infra*.

Gold hydroxides v. GOLD, OXIDES AND HYDROXIDES OF, *infra*.

Gold iodides. Two are known,  $\text{AuI}$  and  $\text{AuI}_2$ .

**Aurous iodide AuI**. A citron-yellow powder, insol. cold, sl. sol. hot, water. Formed by adding  $\text{HIAq}$  to  $\text{Au}_2\text{O}_3$ , I being set free in the reaction; or by adding an equivalent quantity of  $\text{KI}$  in solution, little by little, to  $\text{AuCl}_3\text{Aq}$  ( $\text{AuCl}_3\text{Aq} + 3\text{KIAq} = \text{AuI} + 3\text{KClAq} + 2\text{I}$ ). Decomposed at  $120^\circ$  to  $\text{Au}$  and  $\text{I}$ ; decomposed by  $\text{KOHaq}$  with ppn. of  $\text{Au}$ .  $[\text{AuI}] = -5,520$  (Th. 3, 412).

**Auric iodide AuI<sub>2</sub>**. A dark-green pp. formed by adding  $\text{AuCl}_3\text{Aq}$  little by little, to  $\text{KIAq}$ . When less than  $\text{AuCl}_3$  is added to  $4\text{KI}$  a dark-green liquid is formed, and then a pp. which dissolves on shaking; on then adding a little more  $\text{AuCl}_3\text{Aq}$  the liquid is decolourised and  $\text{AuI}_2$  is ppd. (probably (1)  $4\text{KIAq} + \text{AuCl}_3\text{Aq} = 3\text{KClAq} + \text{KAuI}_2\text{Aq}$  and (2)  $3\text{KAuI}_2\text{Aq} + \text{AuCl}_3\text{Aq} = 3\text{KClAq} + 4\text{AuI}_2$ ).  $\text{AuI}_2$  is very unstable; exposed to the air it changes to  $\text{AuI}$ . It combines with  $\text{HI}$ , but little is known of the properties of the compound; with  $\text{KI}$  it forms  $\text{KAuI}_4$ .

**Potassium auro-iodate** or **iodo-aurate**  $\text{KAuI}_4$ . Black, lustrous, four-sided prisms; formed by dissolving  $\text{AuI}_2$  in  $\text{KIAq}$ , or by mixing  $\text{AuI}_2$  and  $\text{KIAq}$  in the ratio  $\text{AuI}_2:4\text{KI}$ , and allowing the liquid to crystallise. Soluble, with partial decomposition, in water. Decomposed by heat to  $\text{Au}$  and  $\text{KI}$  (cf. Johnston, P. M. [3] 9, 266).  $[\text{AuI}_4\text{Aq}, 3\text{KIAq}] = 45,660$  (Th. 3, 411).

Gold, oxides and hydroxides, *cf.* Three oxides of  $\text{Au}$  have been isolated: **aurous oxide**  $\text{Au}_2\text{O}$ , **auro-auric oxide**  $\text{Au}_2\text{O}$ , and **auric oxide**  $\text{Au}_2\text{O}_3$ . Aurilic hydroxide  $\text{Au}_2\text{O} \cdot \text{OH}$  (or  $\text{Au}_2\text{O}_2(\text{OH})_2$ ) has been obtained, and perhaps one or two other hydroxides intermediate between  $\text{Au}_2\text{O} \cdot \text{OH}$  and  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . There is still doubt as to the isolation of auric hydroxide  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . Oxides of  $\text{Au}$  containing more  $\text{O}$  than  $\text{Au}_2\text{O}_3$  have been described, but according to Krüss none of these exists (v. Krüss, B. 19, 2541; references to older papers

are given by Krüss). The hydrate  $\text{Au}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  described by Raschig (A. 235, 341) does not exist according to Krüss.

**Aurous oxide**  $\text{Au}_2\text{O}$ . This oxide is best prepared by adding  $80\text{Aq}$ , drop by drop, to  $\text{KAuBr}_3\text{Aq}$  kept at  $0^\circ$  until the red colour just disappears, pouring off the liquid, warming the residual  $\text{AuBr}$  with  $\text{KOHaq}$ , washing the ppd. hydrated  $\text{Au}_2\text{O}$  with boiling water, and drying over  $\text{P}_2\text{O}_5$  (Krüss, B. 19, 2543).  $\text{Au}_2\text{O}$  is a greyish-violet solid; when freshly ppd. it is somewhat soluble in cold water, but is ppd. on boiling; also slightly soluble in  $\text{KOHaq}$ ; soluble in  $\text{HClAq}$  or  $\text{HBrAq}$  with separation of  $\text{Au}$ ; unacted on by other acids; decomposed at c.  $250^\circ$  to  $\text{Au}$  and  $\text{O}$ . Solutions of  $\text{Au}_2\text{O}$  in water give a marked absorption-spectrum (Krüss, l.c.). Raschig (A. 235, 341) describes bodies produced by reactions between aurous oxide and ammonia, and the same oxide and methylamine; when conc.  $\text{NH}_3\text{Aq}$  is added to  $\text{Au}_2\text{O}$  suspended in water, a black explosive compound,  $\text{NaN}_3\text{NH}_2$ , is obtained, and when this is boiled with water or dilute acids triauramine,  $\text{NAu}_3$ , is produced;  $\text{NH}_3\text{Me}$  forms  $\text{NMeAu}_3$ .

**AURO-AURIC OXIDE**  $\text{AuO}$  (or  $\text{Au}_2\text{O} \cdot \text{Au}_2\text{O}_3$ ). According to Krüss (B. 19, 2544) this oxide is best obtained by heating  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$  (v. *infra*) to  $160^\circ$ .  $\text{AuO}$  is described as a dark olive-brown powder; very hygroscopic, and must be kept over  $\text{P}_2\text{O}_5$  (Krüss; v. also Schottländer, A. 217, 312). Conc.  $\text{NH}_3\text{Aq}$  acting on  $\text{AuO}$  is said to form the very explosive body *sesquihydratrylamine*  $\text{NH}_3 \cdot \text{N}(\text{AuOH})_2$  (Raschig, A. 235, 341).

**Auric oxide**  $\text{Au}_2\text{O}_3$ .  $\text{AuCl}_3\text{Aq}$  is obtained by decomposing 1 pt.  $\text{AuCl}$  with 50 pts. water and filtering; the liquid is heated to boiling and *magnesia alba* (not *usta*) is added until the red colour of the liquid disappears; the pp. of  $\text{Au}_2\text{O}_3$  is filtered off, suspended in 20 pts. water, and kept in contact with 10 pts.  $\text{HNO}_3\text{Aq}$ , S.G. 1.4, for 12 hours; the residue is then digested at  $100^\circ$  for 6 hours, with reversed condenser attached, with  $\text{HNO}_3\text{Aq}$  and water as before; the residue from this digestion is washed with hot water until every trace of  $\text{HNO}_3$  is removed; the  $\text{Au}_2\text{O}_3$  is then dried and very carefully heated ( $?$  to under  $100^\circ$ ; the directions given by Krüss are not clear).  $\text{Au}_2\text{O}_3$  gives off  $\text{O}$  at c.  $110^\circ$ ; at  $160^\circ$   $\text{AuO}$  remains; at  $250^\circ$   $\text{Au}$  remains. It is easily reduced to  $\text{Au}$ .

When moist  $\text{Au}_2\text{O}_3$  is treated with excess of  $\text{NH}_3\text{Aq}$ , or when excess of  $\text{NH}_3\text{Aq}$  is added to  $\text{AuCl}_3\text{Aq}$  and the pp. is suspended in boiling  $\text{NH}_3\text{Aq}$ , or in water containing a little  $\text{KOH}$ , and then allowed to dry, a yellowish-brown solid, with a tinge of purple, is obtained, which explodes loudly when struck by a hammer or when heated to a little above  $100^\circ$ ; the products of the decomposition are  $\text{Au}$ ,  $\text{NH}_3$ ,  $\text{N}$ , and  $\text{H}_2\text{O}$ . This substance is generally known as *fulminating gold*. Dumas (A. Ch. [2] 44, 167) gave to it the formula  $(\text{AuN} \cdot \text{NH}_3)_2 \cdot 3\text{H}_2\text{O}$ ; this is confirmed by Raschig (A. 235, 341) for the body obtained by the action of  $\text{NH}_3\text{Aq}$  on  $\text{Au}_2\text{O}_3$ , but R. says that the product of the action of  $\text{NH}_3\text{Aq}$  on  $\text{AuCl}_3\text{Aq}$  is a mixture of the preceding *auric diamine* with *auric imido-chloride*,  $\text{NH}_4\text{AuCl}$ . Dilute  $\text{H}_2\text{SO}_4\text{Aq}$  with fulminating gold forms a very explosive body,  $(\text{AuN} \cdot \text{H}_2)_2 \cdot \text{H}_2\text{SO}_4$  (R.).

**AURIC HYDROXIDES**. According to Krüss (B.

19, 2546) the normal hydroxide

$\text{Au}_2\text{O}_3 \cdot 3\text{H}_2\text{O} (= \text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O})$  is obtained by ppg.  $\text{AuCl}_3\text{Aq}$  by *magnesia alba*, and removing the excess of *magnesia* by  $\text{HNO}_3\text{Aq}$  (for details v. *supra*, *AURIC OXIDE*); Krüss does not say at what temperature the pp. must be dried, nor does he give analyses. When this pp. is kept for some weeks over  $\text{P}_2\text{O}_5$ , the hydroxide  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O} (= \text{Au}_2\text{O}_3 \cdot \text{O} \cdot \text{H}_2)$  is obtained (Krüss). Schottländer (A. 217, 312) failed to isolate  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ; the highest percentage of water he obtained agreed with the formula  $2\text{Au}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , and the lowest with the formula  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . Schottländer (l.c.) by decomposing  $\text{AuSO}_4$  (v. *SULPHATES*) by water obtained the compound  $3\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O} (= \text{Au}_2\text{O}_3 \cdot \text{O} \cdot \text{H}_2)$ . These hydroxides, or hydrated oxides, yield Au when heated to c.  $250^\circ$  (cf. also Pelletier, A. Ch. [3] 15, 113; Fremy, A. Ch. [3] 31, 478; Thomsen, Th. 3, 391).

Moist auric oxide (?  $\text{Au}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ) is a weak base; it dissolves in conc.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3\text{Aq}$  but the solutions are decomposed by water with ppn. of hydrated  $\text{Au}_2\text{O}_3$ . Schottländer (A. 217, 312) obtained  $\text{Au}(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$  by dissolving the hydrated oxide in  $\text{HNO}_3\text{Aq}$ , S.G. 1.492, at  $20^\circ$ , heating to  $100^\circ$ , separating from ppd. Au, and crystallising by surrounding by a freeing mixture; by heating this acid nitrate to above  $73^\circ$  he obtained the normal nitrate  $\text{Au}(\text{NO}_3)_3 \cdot x\text{H}_2\text{O}$ . The same chemist obtained the sulphates  $\text{Au}_2\text{O}_3 \cdot \text{HSO}_4$  and  $\text{AuSO}_4$  from the nitrate. Hydrated auric oxide dissolves in alkalis, and from such solutions salts have been obtained known as *aurates*, e.g.  $\text{KAuO}_2 \cdot 3\text{H}_2\text{O}$ . These salts are very easily reduced to Au (v. *AURATES*, vol. i. p. 363). Thomsen (Th. 3, 411) gives the following thermal data:  $[\text{Au}^+\text{H}^+ \cdot 4\text{HClAq}] = 22,970$ ;  $[\text{Au}^+\text{H}^+ \cdot 4\text{HBrAq}] = 36,780$ ;  $[\text{Au}^+\text{H}^+ \cdot 3\text{HClAq}] = 18,440$ ;  $[\text{Au}^+\text{H}^+ \cdot 3\text{HBrAq}] = 29,080$ ;  $[\text{Au}^+\text{O}^+ \cdot \text{H}^+\text{O}] = -13,190$ .

Gold phosphide  $\text{Au}_3\text{P}_2$ . A grey solid, S.G. 6.67, formed by gently heating Au in P vapour; decomposed by heat (Schrötter, W. A. B. 1849, 801).

Gold purple. A name given to *purple of Cassius*, which is probably a mixture of  $\text{SnO}_2$  with finely divided Au (v. *TIN, OXIDES OR*).

Gold, salts of. Few compounds have been isolated produced by replacing H of acids by Au; those which are known are very easily reduced, like all the compounds of Au. The normal nitrate and sulphate  $\text{Au}(\text{NO}_3)_3$ , and  $\text{AuSO}_4$ , have been isolated (v. *supra*); also some basic nitrates and sulphates, and a few double salts, e.g. gold-ammonium sulphite and gold-ammonium thiosulphate (v. *NITRATES, SULPHATES, &c.*).

Gold selenide. The pp. obtained by adding  $\text{H}_2\text{Se}$  to solutions of Au is probably a selenide (Berzelius, P. 8, 173).

Gold selenocyanides v. p. 348.

Gold sulphides. Two sulphides,  $\text{Au}_2\text{S}$  and  $\text{AuS}$ , have been isolated; these sulphides form thio- salts by reacting with alkaline sulphides, but the salts have scarcely been examined. When  $\text{H}_2\text{S}$  is passed into  $\text{AuCl}_3\text{Aq}$ , kept at  $100^\circ$ , Au is ppd.; if local cooling takes place the pp. contains varying proportions of combined S, but no definite compound is produced (L. Hoffmann & Krüss, B. 20, 2369).

Aurous sulphide  $\text{Au}_2\text{S}$ . Obtained by passing  $\text{H}_2\text{S}$  into a solution of  $\text{KAuCy}$ , and then adding  $\text{HClAq}$ . The  $\text{KAuCy}$  was prepared by decolorising  $\text{AuCl}_3\text{Aq}$  by  $\text{KCy}$ , concentrating at  $100^\circ$ , adding dilute  $\text{HClAq}$ , evaporating, and washing the pp. with hot water. The  $\text{KAuCy}$  was dissolved in  $\text{KCyAq}$ ; the liquid was saturated with  $\text{H}_2\text{S}$ , excess of  $\text{HClAq}$  was added, and the whole was heated to boiling. The grey pp. which formed was washed with  $\text{HClAq}$ , then with  $\text{C}_2\text{H}_5\text{O}$ , ether, and  $\text{CS}_2$ , in succession, and finally with ether (L. Hoffmann & Krüss, B. 20, 2373).  $\text{Au}_2\text{S}$  is a brownish-black powder; when freshly ppd. it dissolves in water, but after drying it is insoluble in water, and not decomposed by boiling dilute  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$ . Dissolved by  $\text{BrAq}$ , forming  $\text{AuBr}$ , and  $\text{H}_2\text{SO}_4$ ; oxidised readily by *aqua regia*, &c. It is not acted on by  $\text{KOHAc}$  even at  $100^\circ$ ; slowly dissolved by alkaline monosulphides, easily by alkaline polysulphides, with formation of thio- salts of Au.  $\text{Au}_2\text{S}$  is soluble in  $\text{KCyAq}$  and is reppd. by  $\text{HClAq}$ . It is completely decomposed by heating to  $240^\circ$  (H. a. K.).

Auro-auric sulphide  $\text{AuS} (= \text{Au}_2\text{S} \cdot \text{Au}_2\text{S}_3)$  (L. Hoffmann & Krüss, B. 20, 2704). Obtained by passing  $\text{H}_2\text{S}$  into cold  $\text{AuCl}_3\text{Aq}$  until the liquid is colourless, washing the pp. repeatedly, by decantation, with water, then with absolute alcohol, dry ether, and  $\text{CS}_2$ , successively, and finally with ether, and drying at  $120^\circ$ – $130^\circ$  ( $8\text{AuCl}_3\text{Aq} + 9\text{H}_2\text{S} + 4\text{H}_2\text{O}$

$= 8\text{AuS} + 24\text{HClAq} + \text{H}_2\text{SO}_4\text{Aq}$ ).  $\text{AuS}$  is a black powder; when finely divided it transmits reddish light. Heated to  $140^\circ$ – $150^\circ$ , SO, is evolved, and at  $250^\circ$ – $270^\circ$  all S is removed, without the intermediate production of  $\text{Au}_2\text{S}$ .  $\text{AuS}$  is insoluble in all acids except *aqua regia*; it is gradually oxidised by  $\text{BrAq}$  to  $\text{AuBr}$ , and  $\text{H}_2\text{SO}_4$ ; it is dissolved by alkaline sulphides; acids ppt.  $\text{AuS}$  from these solutions. Conc.  $\text{KOHAc}$  has no action when cold, but on heating Au is ppd. and K aurate and thio-aurate go into solution.

H. a. K. (l.c.) have repeated the experiments of Berzelius, Oberkampf, Yorke, and others, but have failed to obtain any other sulphides of gold except  $\text{Au}_2\text{S}$  and  $\text{AuS}$ . (For references to the older memoirs, v. H. a. K., l.c.)

Sodium aurosulphide  $\text{NaAuS}_4 \cdot \text{H}_2\text{O}$ . Monoclinic prisms; very easily decomposed in air; obtained by fusing together Au,  $\text{Na}_2\text{S}$ , or  $\text{Na}_2\text{CO}_3$ , and S, lixiviating with water in an atmosphere of N, and evaporating in the same atmosphere *in vacuo*.

Gold sulphocyanides v. p. 350.

Gold telluride. Probably obtained by ppg.  $\text{AuCl}_3\text{Aq}$  by  $\text{H}_2\text{Te}$  (Berzelius, P. 8, 178).

M. M. P. M.

GOSSYPOSE is identical with RAFFINOSE.

GRAMININ  $6\text{C}_6\text{H}_{11}\text{O}_5\text{aq}$ , [209]. S.G. 1.592.  $[\alpha]_D = -38.89^\circ$ .  $\alpha$ -S. 22.8 at  $10^\circ$ . A carbohydrate found in the roots of *Trisetum alpestre* and other plants (Ekstrand & Johanson, B. 21, 597).

GRANATINE. An alkaloid in the bark of the root of the Pomegranate (Durand, J. Ph. [4] 28, 168).

GRANDIFLORINE. Mol. w. 286.4. Obtained from the fruit of *Solanum grandiflorum* by extracting with water and alcohol. White powder giving the usual alkaloid reactions. Conc.  $\text{H}_2\text{SO}_4$  and a little  $\text{MnO}_2$  give a yellow colouration.

turning green and then violet (Domingos Freire, C. R. 105, 1074).

**GRANULOSE** v. STARCH.

**GRAPHITE**, a form of carbon; v. vol. I. pp. 685-687.

**GRAPHITIC ACID**  $C_6H_4O_3$ . Formed in small quantity in the electrolysis of mineral acids and salts when the positive pole is pure graphite (Bartoli a. Papasogli, G. 12, 114; 13, 37).

**Preparation**.—Graphite, purified by boiling with acids and fusion with caustic potash, is intimately mixed with  $KClO_3$  (3 pts.); the strongest nitric acid is added in sufficient quantity to render the mixture fluid; and the whole is either exposed to sunshine or heated to  $60^\circ$  for 3 or 4 days. When no more yellow vapours are evolved, the mixture is shaken into a large quantity of water, and the undissolved portion washed by decantation, dried at  $100^\circ$ , and treated with  $KClO_3$  and  $HNO_3$ , as before. This process is repeated three or four times, the residue being graphitic acid (Brodie, A. 114, 6).

**Properties**.—Thin transparent yellow crystals; sl. sol. pure water, insol. water containing acids or salts. When heated it explodes with incandescence, giving off gas and leaving a black residue. When suspended in petroleum (boiling at  $270^\circ$ ) and heated, water comes over between  $100^\circ$  and  $200^\circ$ ,  $CO_2$  being also evolved; the petroleum acquires a deep-red colour, and a black carbonaceous residue ( $C_{22}H_{10}O_7$ ?) is left. When a solution of ammonium or potassium sulphide is poured upon graphitic acid it decomposes with decrepitation, forming a graphitoid substance with metallic lustre. Acid solutions of cuprous and of stannous chloride behave in like manner. Gottschalk (Z. 1865, 652) represents graphitic acid by the formula  $C_6H_4O_3$ .

**Salts**.—When graphitic acid is shaken with aqueous ammonia it is transformed into a transparent jelly, without dissolving; after adding acids and drying *in vacuo* the residue has the same weight as the original graphitic acid. Moist graphitic acid shaken up with baryta-water, washed, and dried at  $100^\circ$  yields a compound containing 21.1 p.c. Ba; after being suspended in water and decomposed by a stream of  $CO_2$  the salt, dried at  $100^\circ$ , contains 13.3 p.c. Ba. This may be  $Ba(C_6H_4O_3)_2$ . It is hygroscopic and detonates when heated.

**Nitro-graphitic acid**  $C_6H_3NO_5$ . An amorphous brown substance got by treating graphite from iron (Spiegeleisen) with  $HNO_3$  (Schützenberger a. Bourgeois, B. 8, 547). Sol. water, nitric acid, alkalis, and alcohol, insol. solutions of salts.

**GRAPHON**, a name given by Brodie to a supposed form of carbon of which graphitic acid was a compound (v. vol. I. p. 687).

**GRATIOLIN**  $C_{28}H_{48}O_8$ . A glucoside occurring in *Gratiola officinalis* (Marchand, J. Chim. Méd. 1846, 367; Walz, Jahrb. pr. Pharm. 21, 1). Amorphous substance, insol. ether, sl. sol. water, v. sol. alcohol. Conc.  $H_2SO_4$  forms a purple solution, the colour being destroyed by water. Its aqueous solution is ppd. by tannin. Boiling dilute  $H_2SO_4$  splits it up into a sugar, gratioletin  $C_{12}H_{22}O_{11}$ , a crystallisable substance insol. water and ether, and gratioleteretin  $C_{16}H_{26}O_8$ , a resin, insol. water, sol. ether.

#### Gratiosolin

occurring in *Gratiola officinalis*. Easily resolved by acids, alkalis, and even PbO into glucose an gratioletin  $C_{12}H_{22}O_{11}$ , a substance soluble in water and ppd. by tannin. Gratiosoletin is further resolved by boiling with dilute acids into glucose and a resinous mixture of gratioletereti  $C_{16}H_{26}O_8$ , sol. ether, and gratioletereti hydrate  $C_{16}H_{26}O_{11}$ , insol. ether. It need hardly be observed that all these formulæ are extremely doubtful.

**GRAVITY, SPECIFIC**, synonymous with relative density, v. p. 871.

**GREVILLEA GUM**. Occurs on the bark of *Grevillea robusta*. Yellowish-red, slightly translucent mass; swells up in water, forming a white emulsion, whence alephol ppts. the gum, leaving 6 p.c. of a red resin in solution. If soaked in water containing a little KOH, lime, or  $K_2CO_3$ , the resulting solution gelatinises on addition of  $FeCl_3$ . The aqueous solution is levorotatory gives no pp. with lead acetate, but a blue gelatinous pp. with  $CuSO_4$ . It does not reduce Fehling's solution. It is oxidised by  $HNO_3$  to mucic and a little oxalic acid. Boiling dilute  $H_2SO_4$  forms a sugar (G. Fleury, J. Ph. [5] 9, 479).

**GUAIACENE**  $C_{12}H_{10}$  (118°). Obtained by distilling gum guaiacum. Identical with TROLIC ALDEHYDE (q. v.).

**GUAIACOL** v. Methyl derivative of PYROCATECHIN.

**GUAIACUM**. *Resina guajaci sativa*. A resin which exudes from the stem of *Guajacum officinale*, a tree growing in the West Indies. It is composed of yellowish-brown lumps usually covered by a greenish-grey powder which renders it opaque. It is brittle. S.G. 1.206 to 1.226. When heated it emits an odour somewhat like that of gum benzoin. Alcohol dissolves about 90 p.c. of the resin, the solution being ppd. by water. Ether and oil of turpentine dissolve much of it. It is nearly insol. water. It dissolves in alkalis.  $H_2SO_4$  dissolves it, forming a splendid red solution, which yields a violet pp. with water; alcohol first colours the liquid violet-blue, and in larger quantity imparts to it a dirty bluish-green tint (Schiff, A. 111, 372). Both the powdered resin and its alcoholic solution turn green when exposed to the air and light (especially violet rays). The alcoholic solution is coloured blue by nitrous fumes, by  $CrO_3$ , by ozone, by chlorine, by  $K_2FeCy_6$ , by  $AuCl_3$ , by  $KMnO_4$ , by  $MoO_3$ , and by  $FeCl_3$ ; the blue colour is removed by  $SO_2$ . Guaiacum tincture is coloured blue by concentrated, but not by dilute, cupric sulphate solution. Even dilute  $CuSO_4$ , in presence of HCl or of organic nitriles, also colour tincture of guaiacum blue (Schörbein, Fr. 8, 67; Schaer, Fr. 9, 430). According to Schön (Fr. 9, 210) guaiacum tincture is coloured blue by a dilute solution of  $CuSO_4$  in presence of  $NH_4Cl$ ,  $BaCl_2$ ,  $NH_4Br$ ,  $KI$ ,  $KCy$ , and  $NH_4F$ . Schön also observes that guaiacum resin is coloured blue by solid lead acetate, by solid  $CaCl_2$ , by solid  $BaCO_3$ , on addition of a little  $HClAq$ , by  $MnCl_2$ , by mercurous nitrate, by a conc. solution of sodium sulphocyanide, and by cupric chloride even in very dilute solutions. Arterial blood colours tincture of guaiacum blue. According to Schörbein (J. pr. 102, 164) exposure to light deprives tincture of guaiacum of the power of colouring

turned blue by ozone. Heat also deprives the resin of this property (Hager, *Fr.* 26, 261). Potash-fusion forms protocatechuic acid from guaiacum. Dry distillation forms tiglic aldehyde  $C_8H_{10}O$  (118°), guaiacol  $C_8H_8(OH)(OMe)$  (200°), creosol  $C_8H_8Me(OH)(OMe)$ , and pyroguaiacin  $C_{10}H_{10}O_2$  [181°] (Hlasiwetz, *A.* 106, 361). Distillation with zinc-dust forms creosol, toluene, *m*- and *p*-xylene,  $\psi$ -cumene, and guaiene  $C_{12}H_{12}$  (Bötsch, *M.* 1, 616). Alkalis extract guaiaretic acid from guaiacum (Unverdorben, *P.* 16, 369). According to Hadelich (*J. pr.* 87, 321) guaiacum also contains guaiaconic acid (sol. ether), and a resin  $C_{12}H_{12}O$ , or  $C_{12}H_{10}O_2$  (insol. ether) [200°], sol. alkalis and reppd. by acids.

**Guaiaretic acid**  $C_{12}H_{10}O_4$ . [75°-80°]. Powdered guaiacum is boiled with milk of lime for half an hour, and the dried insoluble residue exhausted with hot alcohol; the alcoholic solution is evaporated and the residue dissolved in warm aqueous NaOH (S.G. 1.3). On cooling, sodium guaiarotate separates, and may be purified by recrystallisation. The free acid is then got by adding HClAq (Hlasiwetz & Gilm, *A.* 119, 266; cf. Thierry, *J. Ph.* 27, 381; Hlasiwetz, *A.* 112, 182).

**Properties.**—Brittle, concentrically grouped needles (from HOAc). Colourless; permanent in the air. Sol. alcohol, ether, hot HOAc, and  $CS_2$ . Sol. KOHAq; insol.  $NH_4$ Aq. Ppd. by adding  $NH_4Cl$  to its solution in KOHAq. Ppd. as a resin by adding water to its alcoholic solution. Its alcoholic solution is levorotatory, and is coloured grass-green by  $FeCl_3$ . Chlorine-water does not colour the alcoholic solution either green or blue. The aqueous solution is not coloured blue by fuming  $HNO_3$ . When slowly distilled it yields guaiacol and pyroguaiacin  $C_{10}H_{10}O_2$ . [183°]. Potash fusion gives protocatechuic acid. When bromine is dropped into a solution of guaiaretic acid in  $CS_2$ , there is formed  $C_{22}H_{14}Br_2O_4$ , which crystallises from alcohol in needles.

**Salts.**—The guaiarates of the alkalis are crystallisable; those of the alkaline earths are amorphous pps. The neutral salts are stable only in presence of alkali; when boiled with water they are converted into acid salts.— $K_2A$  2aq: scales (from alcohol).— $K_2A$  3aq.— $HKA$  1aq: obtained by boiling the preceding salt with dilute alcohol; crystalline pp.— $Na_2A$  2aq: shining laminae.— $NaHA$  1aq: laminae.— $BaA$  2aq.— $Pb_2C_{12}H_{10}O_4$ : amorphous pp.

**Guaiaconic acid**  $C_{10}H_{10}O_3$  (?). [95°-100°]. Remains in the mother liquor from which sodium guaiarotate (*v. supra*) has crystallised (Hadelich, *J. pr.* 87, 321). The solution is evaporated, the residue extracted with alcohol, and the alcoholic solution treated with  $CO_2$ . Amorphous. V. sol. alcohol, ether, chloroform, and HOAc. Levorotatory. When heated with HClAq at 180° it forms MeCl and pyrocatechin (Hörzig, *M.* 3, 125, 823). Nitrous acid gas passed into its ethereal solution forms di-nitro-guaiacol. The K and Na salts are sol. water and alcohol; the Ba and Pb salts are insoluble.

**GUAIENE**  $C_{12}H_{12}$ . [98°]. Obtained by distilling resin of guaiacum or pyroguaiacin with zinc-dust (Bötsch, *M.* 1, 618; Wieser, *M.* 1, 602). Lemine (by sublimation) with blue fluorescence.

Volatile with steam. Sol. alcohol and ether. Conc.  $H_2SO_4$  forms a green solution; on adding water the hydrocarbon is not reppd.  $CrO_3$  in HOAc forms guaiene-quinone  $C_{12}H_8O_2$ , which by sublimation forms lemon-yellow needles, [122°], m. sol. water, insol.  $NaHSO_4$ Aq. Guaiene forms with picric acid a compound crystallising in slender needles, [123°], v. sl. sol. alcohol.

**GUAIOL v. TIGLIC ALDEHYDE.**

**GUANAMINE.** The substance to which this name was given by Nencki, was subsequently called by him FORMOGUANAMINE (*q. v.*).

**DIGUANIDE**  $C_2H_2N_4$ , i.e.  $\begin{matrix} NH: C(NH_2) \\ | \\ NH: C(NH_2) \end{matrix} > NH$ .

**Biguanide.** Guanidyl-guanidine.

**Formation.**—1. By heating a salt of guanidine with cyanamide; the yield being small (Rathke, *B.* 12, 776).—2. By the action of  $PCl_5$  or bromine on a mixture of thio-urea and guanidine sulphocyanide; the yield is very small.—3. By heating di-cyan-di-amide with an ammoniacal solution of  $Ca(OH)_2$  at 110°; the resulting copper derivative being decomposed by  $H_2S$  (Herth, *M.* 1, 88).

**Preparation.**—An alcoholic solution of di-cyandiamide is heated with ammonium chloride in a sealed tube for 8 hours at 105° (Smolka & Friedreich, *M.* 9, 228).

**Properties.**—The free base, liberated from its sulphate by baryta, is amorphous and alkaline in reaction. It expels ammonia from its salts. Boiling diluted  $H_2SO_4$  splits it up into  $NH_3$  and  $CO_2$ .

**Salts.**— $B^+H_2SO_4$ aq: crystals, v. sol. water.— $B^+H_2SO_4$ aq: from the sulphate of the copper derivative and  $H_2S$  (Emich, *M.* 4, 1409); large colourless crystals, with neutral reaction, v. sol. water.—The hydrochloride and nitrate crystallise in soluble needles.— $B^+H.PtCl_4$  2aq: soluble crystals.—Copper derivative  $(C_2H_2N_4)_2Cu$  2aq. Obtained by heating an ammoniacal solution of cupric oxide with di-cyan-di-amide (Herth, *M.* 1, 88). Large flat prisms of brick-red colour; v. sl. sol. cold, sol. hot, water, forming a deep-violet solution, turned blue by acids. Alkaline in reaction.— $(C_2H_2N_4)_2CuH_2SO_4$  3aq: slender red needles, sl. sol. water. Formed by adding ammoniacal  $CuSO_4$  to a solution of a salt of diguanide.

**References.**—*ISO-BUTYL, ETHYL-, METHYL-, and PHENYL DIGUANIDE.*

**GUANIDINE**  $C_2H_2N_4$ , i.e.  $NH:C(NH_2)_2$ . Mol. w. 59.

**Formation.**—1. Together with parabanic acid, and small quantities of xanthine, oxaluric acid, and urea, by the action of HCl (S.G. 1.10) and  $KClO_4$  (12 g.) on guanine (20 g.) in the cold (Strecker, *A.* 118, 151).—2. By heating biuret to 165° in dry gaseous HCl (Finckh, *A.* 124, 335).—3. By heating chloro-piuric for several hours at 100° with a strong alcoholic solution of ammonia (Hofmann, *Z.* [2] 2, 1073; 4, 721; *B.* 1, 145; *A.* 139, 107).—4. In small quantity by the action of aqueous ammonia at 150° on ortho-carbonic ether (Hofmann, *A.* 139, 111).—5. Together with urea by the action of dry ammonia on carbonyl chloride  $COCl_2$  (Bouchardat, *C. R.* 69, 961; Fenton, *C. J.* 86, 793).—6. By heating cyanamide in alcoholic solution with ammonium chloride at 100° (Erlenmeyer, *Z.* [2] 7, 28; *A.* 146, 259).—7. By heating cyanogen

iodide with alcoholic  $\text{NH}_3$  for 8 hours at  $100^\circ$  (Bannow, B. 4, 181). According to Ossikovsky (B. [2] 18, 161) other products, including a volatile fatty acid, are formed at the same time. 8. Together with urea, ammelide, and biuret, by the electrolysis of a solution of ammonia with carbon electrodes (Millot, B. [2] 46, 244). 9. Among the products of the oxidation of egg albumen by  $\text{KMnO}_4$  in presence of magnesia (Lossen, A. 201, 869).

**Preparation.**—Dry ammonium sulphocyanide is heated for 20 hours at  $180^\circ$ – $190^\circ$ . The residue consists mainly of guanidine sulphocyanide, no gaseous product being given off. The guanidine sulphocyanide is purified by recrystallisation from water or alcohol, and is converted into the carbonate by mixing a solution of it (100 g.) with a solution of  $\text{K}_2\text{CO}_3$  (58 g.), evaporating, and dissolving out the potassium sulphocyanide with alcohol. The guanidine carbonate is then recrystallised from water, and the base liberated by dissolving in the calculated quantity of dilute  $\text{H}_2\text{SO}_4$  and adding the calculated quantity of baryta (Delitsch, J. pr. 2] 8, 240; 9, 1; Volhard, J. pr. [2] 9, 10).

**Properties.**—Crystalline, strongly alkaline mass, having a caustic taste. When exposed to the air it deliquesces and absorbs carbonic acid.

**Reactions.**—1. When boiled with baryta water it gives ammonia and urea; the urea subsequently breaking up into  $\text{CO}_2$  and ammonia (Baumann, B. 6, 1376). Hence boiling concentrated acids and alkalis give only  $\text{CO}_2$  and  $\text{NH}_3$  (Ossikovsky, B. 5, 668).—2. With hypobromite or hypochlorite of sodium, two-thirds of the nitrogen is evolved, one-third remaining behind, probably as cyanate (Fenton, C. J. 35, 14).—3. Benzoic anhydride acting at  $100^\circ$  on guanidine carbonate forms *s*-di-benzoyl-urea [ $210^\circ$ ] (McCreath, B. 7, 1739).—4. With chloro-formic (chloro-carbonic) ether it forms guanidine dicarboxylic ether  $\text{HN}(\text{C}(\text{NH}_2)\text{CO}_2\text{Et})_2$ . This ether is converted by alcoholic ammonia at  $100^\circ$  into guanidine mono-carboxylic ether (so-called guanoline):  $\text{HN}(\text{C}(\text{NH}_2)\text{NHCO}_2\text{Et})$  (M. Nencki, J. pr. [2] 17, 237).—5. When the salts of guanidine with fatty acids are heated there are formed 'guanamines'. Thus guanidine formate forms formo-guanamine  $\text{C}_2\text{H}_5\text{N}$ , while guanidine acetate gives acetoguanamine  $\text{C}_2\text{H}_5\text{N}$  (v. infra).—6. Salts of guanidine, heated with cyanamide form diguanide (v. supra).—7. When fused with urea, guanidine carbonate forms guanyl-urea  $\text{C}_2\text{H}_5\text{N}_3\text{O}$ . 8. An aqueous solution of guanidine carbonate (2 mols.) boiled with an alcoholic solution of phenanthraquinone forms small colourless prisms of the base  $\text{C}_4\text{H}_7\text{N}_3$ , probably  $\text{C}_4\text{H}_7\text{C}_3\text{N}_3(\text{NH}_2)_3\text{NH}$ .

It is alkaline in reaction, absorbs  $\text{CO}_2$  from the air, and forms a crystalline hydrochloride  $\text{B}^+\text{H}_2\text{Cl}$  (Wense, B. [9] 761).—9. In like manner *densil* (1 mol.) boiled with guanidine carbonate (2 mols.) in dilute alcoholic solution forms benzil-di-guanidine  $\text{C}_2\text{H}_5\text{N}_3$ , which may probably be written  $\text{HN}(\text{C}(\text{NH}_2)_2\text{N}:\text{CPh}:\text{CPh}:\text{N}(\text{NH}_2)_2\text{NH})$ . It forms granular crystals, reacts alkaline, absorbs  $\text{CO}_2$  from the air, and gives a hydrochloride crystal-

lising in long needles, and a platinocyclori  $\text{B}^+\text{H}_2\text{PtCl}_6$ , crystallising in plates (Wense, B. 1 763).—10. When *densil* (1 mol.) is boiled with a smaller quantity of guanidine carbonate (mol.) in aqueous-alcoholic solution, there is formed benzil mono-guanide  $\text{C}_2\text{H}_5\text{N}_3\text{O}$  probably  $\text{O}:\text{CPh}:\text{CPh}:\text{N}(\text{NH}_2)_2\text{NH}$ . This body forms white oblong plates, sol. alcohol, insol. water. It is alkaline in reaction (Wense, B. 1 762).—11. *Aceto-acetic acid* digested in alcoholic solution with guanidine carbonate for a few hours forms 'methyl-guanacil'  $\text{C}_2\text{H}_5\text{N}_3\text{O}$  in  $\text{HN}(\text{C}(\text{NH}_2)\text{NHCO}_2\text{CH}_3)_2$ . This body crystallises from water in prismatic needles; sol. hot, sl. sol. cold, water, v. sl. sol. alcohol (Behrend, B. 19, 219).—12. *Phenyl-thio-carbimide* (8 pts. heated with alcohol and guanidine carbonate (2 pts.) at  $100^\circ$  forms the crystalline compound  $\text{NHPh}:\text{CS}:\text{NH}(\text{NH}_2)_2\text{NH}$  [ $176^\circ$ ] (Bamberger B. 13, 1581; 14, 2638).

**Salts.**— $\text{B}^+\text{HCl}$ : regular needles; v. sol. alcohol. — $\text{B}^+\text{H}_2\text{PtCl}_6$ : yellow needles or prisms, v. sol. water, v. sl. sol. alcohol. — $\text{B}^+\text{HClHgCl}_4$  — $\text{B}^+\text{H}_2\text{AuCl}_4$ : long needles. — $\text{B}^+\text{HBr}$ : from guanidine carbonate (1 mol.) and bromine (3 mols.). Large red prisms which easily lose bromine (Kamenski, B. 11, 619). — $\text{B}^+\text{HI}$ : prisms. — $\text{B}^+\text{HNO}_3$ : ppd. as a crystalline powder by adding  $\text{KNO}_3$  to a solution of the hydrochloride. Formed also by rubbing guanidine sulphocyanide with pure  $\text{HNO}_3$  and filtering before deflagration ensues (Jousselin, C. R. 88, 1086). Laminæ (from hot water); sl. sol. cold water. Mixed with silver nitrate it gives the crystalline compound  $\text{B}^+\text{AgNO}_3$ . —Sulphate crystallises in the regular system and is v. e. sol. water. — $\text{B}^+\text{H}_2\text{CO}_3$ . May be obtained by boiling the sulphocyanide with diluted  $\text{H}_2\text{SO}_4$ , filtering, treating with  $\text{BaCO}_3$ , and allowing the liquid to evaporate spontaneously (Jousselin). Dimetric octahedra or prisms; v. sol. water, insol. alcohol. Permanent in the air. When heated above  $120^\circ$  it gives off water,  $\text{CO}_2$  and  $\text{NH}_3$ , and leaves a yellow residue resembling mellon. —Oxalate  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ : colourless crystals, sl. sol. water. —Lactate forms regular crystals. —Cyanurate  $\text{B}^+\text{C}_3\text{N}_3\text{O}_3\text{H}_3$ : silky needles (Bamberger, B. 20, 68). —Sulphocyanide  $\text{B}^+\text{HSCy}$ . [ $120^\circ$ ]. S. 73 at  $0^\circ$ ; 135 at  $15^\circ$  (Engel, B. [2] 44, 424). Formed as above. Large flexible laminæ with fatty lustre (from water or alcohol). Not deliquescent. At  $150^\circ$  it gives off  $\text{NH}_3$  and leaves melam. Upon this salt mercuric oxide has no action in alcoholic solution, but in aqueous solution it gives a pp. composed thus:  $\text{B}^+\text{HSCN}:\text{Hg}(\text{SCN})_2\text{HgO}$ . The reaction taking place as follows:  $3\text{B}^+\text{HSCN} + 2\text{HgO} + 3\text{H}_2\text{O} = \text{B}^+\text{HSCN}:\text{Hg}(\text{SCN})_2\text{HgO} + 6\text{NH}_3 + 2\text{CO}_2$ . The pp. is converted by acetic acid into a mixed acetate and sulphocyanide of mercury. The same pp. is converted by concentrated  $\text{HCl}$  into crystalline plates of  $\text{CN}(\text{H}_2\text{N})_2\text{HCl}:\text{HgCl}_2$  (Byk, J. pr. [2] 20, 330). Fused guanidine sulphocyanide treated with finely divided lead (got by reducing the oxide by hydrogen) is partially converted into 'cyano-melaminde',  $\text{C}_2\text{H}_5\text{N}_3\text{O}$ , a body which is soluble in water but is separated from the original salt by its insolubility in alcohol. Cyanomelaminde forms salts of melamine when treated with  $\text{HCl}$ ,  $\text{FeCl}_3$  or  $\text{H}_2\text{SO}_4$ . With  $\text{HNO}_3$

it forms the nitrate of ammeline. With  $\text{KMnO}_4$ , it gives melamine (Byk, *J. pr.* [2] 20, 338).

**Nitroso-guanidine**  $\text{CH}_2\text{N}_2\text{O}$  *i.e.*  $\text{NO.N.C(NH}_2)_2$ . Formed by passing nitrous acid gas through dry guanidine nitrate suspended in conc.  $\text{HNO}_3$ . The salt slowly dissolves, and on adding water to the solution, nitroso-guanidine is pptd. in slender needles, which are recrystallised from boiling water (Jousselin, *C. R.* 88, 814). Needles; sl. sol. cold water and alcohol, insol. ether. Boiling conc.  $\text{KOH}$  decomposes it, giving off  $\text{NH}_3$ . Warm conc.  $\text{HNO}_3$  dissolves it, and on cooling the salt  $\text{B'HNO}_3$  separates in large plates; this salt is efflorescent and decomposed by water.  $\text{HCl}$  dissolves nitroso-guanidine yielding slender iridescent plates which are decomposed by water. On dissolving nitroso-guanidine in water, adding a drop of very dilute aqueous  $\text{KOH}$  and a drop of aqueous  $\text{FeSO}_4$ , a purple colour is produced. If alcohol and ether are added to the coloured solution minute dark-red crystals are deposited. Finely divided iron acting on nitroso-guanidine suspended in water at  $40^\circ$  also forms a purple colour, but after some time this disappears,  $\text{NH}_3$  being evolved. The solution evaporated at  $60^\circ$  leaves an unstable sulphur-yellow residue which appears to be  $\text{CH}_2\text{N}_2\text{O}$ .

**Acetoguanamine**  $\text{C}_2\text{H}_4\text{N}_4$  *i.e.*  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{C(NH)} \\ \text{C(NH)} \end{smallmatrix} \text{NH}$  (Weith, *B. 9*, 458), or  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{C(NH)} \\ \text{C(NH)} \end{smallmatrix} \text{N}$  (Claus, *B. 9*, 722). *Ethenyl-*

*diguamide*. *Di-amido-methyl-triazoline*. [ $265^\circ$ ]. Formed by heating dry guanidine acetate for 15 minutes at  $230^\circ$ ; the resulting acetoguanamine acetate being extracted by water and decomposed by  $\text{NaOHAq}$  (Nencki, *B. 7*, 776, 1585). Trimetric laminae; sl. sol. cold, v. sol. hot, water. V. sol. alcohol. Slightly alkaline in reaction. Chlorine passed into acetoguanamine suspended in water forms a granular pp.  $\text{C}_2\text{H}_4\text{Cl}_2\text{N}_4$  (Nencki, *B. 9*, 237). This is insol. water, sol. alkalis; by heating with dilute  $\text{HCl}$  it is converted into an isomeric body which crystallises from dilute acetic acid in needles, is insol. alkalis and forms the salts  $(\text{C}_2\text{H}_4\text{Cl}_2\text{N}_4)_2\text{H}_2\text{PtCl}_6$  and  $\text{C}_2\text{H}_4\text{Cl}_2\text{N}_4\text{AgNO}_3$ .

**Salts**.— $\text{B'HCl}$  2aq: tables or prisms.— $\text{B}_2\text{H}_2\text{PtCl}_6$ : yellow crystalline pp.; v. sol. water.— $\text{B'HNO}_3$ : prisms, v. sol. water.— $\text{B}_2\text{H}_2\text{SO}_4$  2aq: plates, v. e. sol. water.— $\text{B}_2\text{AgNO}_3$ : small plates (from hot water).

**Acetoguanide**  $\text{C}_2\text{H}_4\text{N}_4\text{O}$  *i.e.*  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{C(NH)} \\ \text{C(NH)} \end{smallmatrix} \text{NH}$  or  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{C(OH)} \\ \text{C(NH)} \end{smallmatrix} \text{N}$ .

**Oxy-amido-methyl-triazoline**. Formed by boiling acetoguanamine (1 pt.) with  $\text{KOH}$  (2 pts.) and water (4 pts.) for  $1\frac{1}{2}$  hours, and ppg. with  $\text{HOAc}$  (Nencki, *B. 9*, 233). Crystalline pp. Almost insol. water, alcohol, dilute  $\text{HOAc}$ , and aqueous  $\text{NH}_3$ , v. sol. alkalis and  $\text{HCl}$ .— $\text{C}_2\text{H}_4\text{NaN}_4\text{O}_2$  2aq.— $\text{C}_2\text{H}_4\text{KN}_4\text{O}_2$  2aq.— $\text{C}_2\text{H}_4\text{N}_4\text{OHCl}$ : needles.— $\text{C}_2\text{H}_4\text{N}_4\text{OAgNO}_3$ .

**Acetoguanamide**  $\text{C}_2\text{H}_4\text{N}_4\text{O}$  *i.e.*  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{NH}$  or  $\text{CMe} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{C(OH)} \\ \text{C(OH)} \end{smallmatrix} \text{N}$ .

**Di-oxy-methyl-triazoline**. From acetoguanamine (1 pt.), by warming with conc.  $\text{H}_2\text{SO}_4$  (3 pts.) at  $160^\circ$ . Small needles (from alcohol); v. e. sol. water, acids, and alkalis, sl. sol. alcohol.

On warming with nitric acid (S.G. 1.3) it yields cyanuric acid. Chlorine passed into its aqueous solution forms crystalline  $\text{C}_2\text{H}_4\text{Cl}_2\text{N}_4\text{O}_2$ . Sl. sol. hot water, being decomposed thereby with formation of cyanuric acid.— $\text{B'HCl}$ : needles.— $\text{B}_2\text{H}_2\text{PtCl}_6$  4aq.

**References**.—BROMO-, CHLORO-, OXY-, BENZYL-, ETHYL-, METHYL-, NAPHTHYL-, NITRO-PHENYL-, PHENYL-, TOLYL-, and XYL- GUANIDINES.

#### GUANIDINE CARBOXYLIC ETHER

$\text{C}_2\text{H}_4\text{N}_4\text{O}$  *i.e.*  $\text{HN.C(NH}_2)_2\text{NH.CO.Et}$ . *Guanidine*. [ $115^\circ$ ]. Formed as below. Trimetric laminae (from water or alcohol); the crystals contain aq and melt at  $100^\circ$ ; when anhydrous it melts at  $115^\circ$ .— $\text{B'HNO}_3$ : trimetric prisms.— $\text{B}_2\text{H}_2\text{SO}_4$ .— $\text{B}_2\text{H}_2\text{PtCl}_6$  4aq.

Guanidine dicarboxylic ether  $\text{C}_2\text{H}_4\text{N}_4\text{O}_2$  *i.e.*  $\text{NH.C(NH}_2)_2\text{NH.CO}_2\text{H}$ . [ $162^\circ$ ]. Formed by slowly adding  $\text{ClCO}_2\text{Et}$  to a concentrated alcoholic solution of guanidine (Nencki, *J. pr.* [2] 17, 237). Needles; insol. water, v. sol. alcohol and ether. Alcoholic  $\text{NH}_3$  converts it at  $100^\circ$  into guanidine carboxylic ether.

**GUANIDO-ACETIC ACID**  $\text{C}_2\text{H}_4\text{N}_4\text{O}_2$  *i.e.*  $\text{NH.C(NH}_2)_2\text{NH.CO}_2\text{H}$ . *Glycocyamine*.

Formed by allowing an aqueous solution of glyccoll, cyanamide, and a little  $\text{NH}_3$  to stand for some days (Strecker, *C. R.* 52, 1212). Formed also by heating glyccoll with guanidine carbonate (Nencki a. Sieber, *J. pr.* [2] 17, 477). Crystals, sl. sol. water, insol. alcohol.— $\text{B}_2\text{H}_2\text{PtCl}_6$  8aq.— $(\text{C}_2\text{H}_4\text{N}_4\text{O}_2)_2\text{Cu}$ : blue pp.— $\text{B'HCl}$ : prisms.

By heating to  $160^\circ$  it is split up into water and the hydrochloride of 'glycocyamine'  $\text{C}_2\text{H}_4\text{N}_4\text{O}$  or  $\text{NH.C} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CH}_2 \end{smallmatrix}$ , a base which crystallises in laminae, v. sol. water, and forms the salts  $\text{C}_2\text{H}_4\text{N}_4\text{OHCl}$  and  $(\text{C}_2\text{H}_4\text{N}_4\text{O})_2\text{H}_2\text{PtCl}_6$  2aq.

**GUANIDO-BENZENE p-SULPHONIC ACID**  $\text{C}_2\text{H}_4\text{N}_4\text{SO}_4$  *i.e.*  $\text{SO}_3\text{H.C}_6\text{H}_4\text{NH.C(NH}_2)_2\text{NH}$ . Formed by heating amido-benzene p-sulphonic acid (10 g.) with cyanamide (3 g.), water (200 c.c.) and ammonia (23 drops) at  $100^\circ$  for three days (Ville, *C. R.* 104, 1261). Brilliant needles, v. sl. sol. cold water, insol. alcohol and ether. Neutral to litmus. Decomposes at  $180^\circ$ . Dissolves without alteration in  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$ .  $\text{NaOBr}$  gives a purple colouration, with evolution of nitrogen.

**GUANIDO-BENZOIC ACID**  $\text{C}_2\text{H}_4\text{N}_4\text{O}_2$  *i.e.*  $\text{NH.C(NH}_2)_2\text{NH.C}_6\text{H}_4\text{CO}_2\text{H}$ . *Benzylglycocyamine*.

Formed by allowing an alcoholic solution of m-amido-benzoic acid and cyanamide to stand, after addition of a little ammonia (Griess, *B. 7*, 575). Formed also by boiling the dicyanide of m-amido-benzoic acid with caustic potash (Griess, *B. 3*, 703), and by treating the compound  $\text{NH.C(OEt).NH.C}_6\text{H}_4\text{CO}_2\text{H}$  with conc.  $\text{NH}_3\text{Aq}$  (Griess, *B. 8*, 323). Thin four-sided plates (containing aq); m. sol. hot water. Boiling baryta-water gives m-amido-benzoic acid, m-amido-benzoic acid, urea, and  $\text{NH}_3$ .— $\text{B}_2\text{H}_2\text{PtCl}_6$ .— $\text{B'HCl}$ .

**Reference**.—Vgl. i. p. 462.

Guanido-di-benzoic acid v. vol. i. p. 187.

**GUANIDO-BUTYRIC ACID**  $\text{C}_2\text{H}_4\text{N}_4\text{O}_2$  *i.e.*  $\text{NH.C(NH}_2)_2\text{NH.CHEt.CO}_2\text{H}$ . *Oxybutyrylamine*.

Formed by adding cyanamide and a few drops of  $\text{NH}_3\text{Aq}$  to a cold saturated solution of m-amido-butyric acid.

Crystals are deposited in about a month, and are purified by recrystallisation from water containing a little  $\text{NH}_3$  (Duvillier, *C. R.* 91, 171). Long slender needles, sl. sol. cold water, v. sol. dilute acids, almost insol. alcohol and ether. By boiling with dilute  $\text{H}_2\text{SO}_4$  it is converted into the anhydride  $\text{CHEt} \begin{smallmatrix} \text{NH} \cdot \text{C}(\text{NH}) \\ \text{CO} \cdot \text{NH} \end{smallmatrix}$ , which crystallises from water in long transparent needles (containing aq); sol. alcohol.

**GUANIDO-ETHANE SULPHONIC ACID**  
 $\text{NH}_2\text{C}(\text{NH}_2)\text{NH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{SO}_3\text{H}$ . *Tauro-cyaminate*. [233°]. Prepared by heating taurine (1.578 grm.) with cyanamide (85 grm.), and enough water to dissolve them, for five hours at 120°. Evaporated to crystallisation. The yield is 1.4 grms. (Dittrich, *J. pr.* [2] 18, 76). Hexagonal prisms. Readily sol. water. Insol. alcohol and ether. No salts have been obtained.

**GUANIDO-HEXOIC ACID**  $\text{C}_6\text{H}_{11}\text{N}_3\text{O}_5$ , i.e.  $\text{NH}_2\text{C}(\text{NH}_2)\text{NH} \cdot \text{CH}(\text{CH}_2\text{Pr}) \cdot \text{CO}_2\text{H}$ . *Amido-caprocyamine*. Formed by mixing an aqueous solution of leucine with cyanamide and a few drops of  $\text{NH}_4\text{Aq}$ , and allowing the liquid to stand for some time (Duvillier, *C. R.* 104, 1290). Radiating plates; sl. sol. cold, m. sol. hot, water, sl. sol. alcohol. When boiled with dilute  $\text{H}_2\text{SO}_4$  for several hours it changes to the anhydride  $\text{NH}_2\text{C} \begin{smallmatrix} \text{NH} \cdot \text{CO} \\ \text{NH} \cdot \text{CH} \cdot \text{C}_6\text{H}_9 \end{smallmatrix}$ , which crystallises in groups of needles; S. (alcohol) 17 at 22°; sl. sol. cold, m. sol. hot, water. This anhydride ('amido-caprocyamidine') readily takes up water, reproducing guanido-hexoic acid.

**$\alpha$ -GUANIDO-PROPIONIC ACID** v. ALAKRATIVE.

**$\beta$ -Guanido-propionic acid**  $\text{C}_5\text{H}_9\text{N}_3\text{O}_5$ , i.e.  $\text{NH}_2\text{C}(\text{NH}_2)\text{NH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ . Formed by adding a little  $\text{NH}_4\text{Aq}$  to a solution of  $\beta$ -amido-propionic acid (20 pts.) and cyanamide (7 pts.) (Mulder, *B.* 8, 1261; 9, 1902). Crystals; not decomposed below 200°.  $\text{B}^*\text{HCl}$ : very deliquescent needles.

**$\alpha$ -GUANIDO-VALEERIC ACID**  $\text{C}_6\text{H}_{11}\text{N}_3\text{O}_5$ , i.e.  $\text{NH}_2\text{C}(\text{NH}_2)\text{NH} \cdot \text{CHPr} \cdot \text{CO}_2\text{H}$ . *Oxy-valerocyamine*. From  $\alpha$ -amido-valeric acid, an aqueous solution of cyanamide, and a little  $\text{NH}_3$  (Duvillier, *C. R.* 91, 171). Small cubic crystals, sl. sol. water, v. sl. sol. alcohol; insol. ether. Boiling dilute  $\text{H}_2\text{SO}_4$  converts it into the

anhydride  $\text{C}_6\text{H}_{11}\text{N}_3\text{O}_4$  or  $\text{NH}_2\text{C} \begin{smallmatrix} \text{NH} \cdot \text{CO} \\ \text{NH} \cdot \text{CHPr} \end{smallmatrix}$ , which forms delicate needles (containing  $\frac{1}{2}$  aq); m. sol. water and alcohol.

**GUANILINE** v. GUANIDINE CARBOXYLIC ETHER.

**GUANINE**  $\text{C}_5\text{H}_7\text{N}_5\text{O}_2$  i.e.  $\text{HN} \cdot \text{C} \begin{smallmatrix} \text{NH} \cdot \text{OH} \cdot \text{CNH} \\ \text{NH} \cdot \text{C} \cdot \text{NH} \end{smallmatrix} \text{CO}$  (Fischer, *B.* 15, 455).

Mol. w. 151. Occurs in all kinds of guano, especially in Peruvian guano (Unger, *A.* 51, 395; 59, 58). Constitutes the greater part of the excrement of the garden spider, and found in the green gland of the fresh-water crayfish, and in the Bojanian organ of the pond-mussel (Gorup-Besanez & F. Will, *A.* 69, 117; Griffiths, *Pr.* 88, 187). Found in the pancreas of horses (Scherer, *A.* 112, 257) and oxen (Baginsky, *H.* 8, 396), in the scales of the bleak (Barreswill,

*C. R.* 53, 246), and in the excrement of the heron (Hoppe-Seyler, *Med.-Chem. Unters.* 1871 582). Guanine occurs as a concretion in the knee-joints of pigs suffering from guano-gou (Virchow, *Z.* 1866, 377), and perhaps also in the urine of such pigs (Pecile, *A.* 183, 141). It has also been found to the amount of 5 or 6 p.c. in the sperm of the salmon (Piccard, *B.* 7, 1714) and, together with other bases, in the extract obtained by boiling yeast with water (Schützenberger, *B.* 7, 192). Kossel (*H.* 8, 404) finds guanine in the liver, spleen, and embryonic muscle of oxen.

**Preparation.**—Guano suspended in water is gradually mixed with milk of lime; the liquid is heated to boiling, and the brown solution is strained through a cloth filter, this treatment being repeated till the liquid becomes colourless. Guanine and uric acid remain almost wholly undissolved, and this residue is now repeatedly boiled with carbonate of sodium, and the united solutions are mixed with acetate of sodium, and then with hydrochloric acid in sufficient quantity to produce a strong acid reaction. The pp., consisting of guanine and uric acid, is washed with moderately dilute hydrochloric acid, then boiled with the acid, and the solution of hydrochloride of guanine, filtered from the uric acid, is evaporated. The hydrochloride of guanine thus obtained still contains uric acid, to remove which the guanine is ppd. from the solution by boiling with dilute ammonia, then dissolved in hot nitric acid to decompose the uric acid; and from the nitrate of guanine, which crystallises from this solution, the pure base is ppd. by ammonia (Strecker, *A.* 118, 151). According to Neubauer and Kerner (*A.* 101, 318), pure guanine is most easily obtained by dissolving the compound of guanine with mercuric chloride in very dilute hydrochloric acid, decomposing the compound with  $\text{H}_2\text{S}$ , and ppg. the colourless filtrate with ammonia.

**Properties.**—White amorphous powder, insol. water, alcohol, and ether. It is sl. sol. conc.  $\text{NH}_4\text{Aq}$ , and is deposited as crystals by spontaneous evaporation of the ammoniacal solution (Drechsel, *J. pr.* [2] 24, 44). When guanine is evaporated with fuming  $\text{HNO}_3$  a yellow residue is left, which is turned red by ammonia, and then becomes purple on warming (*cf.* Von Brücke, *M.* 7, 617). A solution of a salt of guanine gives an orange pp. with  $\text{K}_2\text{CrO}_4$  and a brown pp. with  $\text{K}_2\text{FeCy}_4$ . A saturated solution of picric acid gives an orange-yellow pp. (Capranica, *H.* 4, 233).

**Reactions.**—1. *Nitrous acid* converts it into xanthine, imidogen being displaced by oxygen (Strecker, *A.* 108, 141).—2.  $\text{KClO}_4$  and  $\text{HCl}$  form guanidine and parabanic acid, together with smaller quantities of oxaluric acid, xanthine, and urea.—3.  $\text{KMnO}_4$  and  $\text{NaOH}$  at 80° form oxyguanine  $\text{C}_5\text{H}_7\text{N}_5\text{O}_3$ , which may be ppd. by acids as a jelly, insol. water, alcohol, and dilute  $\text{HClAq}$ , sol. alkalis (Kerner, *A.* 103, 251). With ammoniacal  $\text{AgNO}_3$ , oxyguanine gives a silver derivative.

**Salts.**—The compounds of guanine with acids are decomposed by water. Guanine does not appear to form an acetate or formate.— $\text{B}^*\text{HClAq}$ : delicate needles, deposited from a

solution of guanine in hot conc.  $\text{HClAq.}$ — $\text{B'HCl 2aq}$  (Scherer, A. 112, 277).— $\text{B'HCl}_2$ : from guanine and gaseous  $\text{HCl}$ ; gives off half its acid at  $100^\circ$  (Unger).— $\text{B'HBraq}$ : prismatic needles, sl. sol. water, v. sol.  $\text{HIAq.}$ — $\text{B'HClPtCl 2aq (?)}$ : orange-yellow crystals (U.).— $\text{B'H}_2\text{Cl}_2\text{HgCl}_2\text{aq}$ : ppd. when alcoholic  $\text{HgCl}_2$  is added to a strong solution of guanine hydrochloride.— $\text{B'H}_2\text{Cl}_2\text{ZnCl}_2\text{8aq}$ : large crystals, obtained by adding guanine hydrochloride to a strong solution of  $\text{ZnCl}_2$ .— $\text{B'H}_2\text{Cl}_2\text{CdCl}_2\text{9aq}$ .— $\text{B'HNO}_3\text{1}\frac{1}{2}\text{aq}$ : hair-like interlacing needles, deposited from a solution of guanine in boiling  $\text{HNO}_3$  as it cools.— $\text{B'(HNO}_3)_2\text{2aq}$ : short prisms.— $\text{B'_1(HNO}_3)_4\text{4aq}$ .— $\text{B'_1(HNO}_3)_5\text{5aq}$ .— $\text{B'_1H}_2\text{SO}_4\text{2aq}$ : \*obtained by diluting with water a solution of guanine in conc.  $\text{H}_2\text{SO}_4$ . Long needles.— $\text{B'_1(H}_2\text{C}_2\text{O}_4)_2$ : separates as crystals on mixing a solution of guanine hydrochloride with one of ammonium oxalate.—Tartrate  $\text{B'_1(H}_2\text{C}_2\text{O}_4)_2\text{2aq}$ : yellowish radiating nodules.

**Metallic derivatives**  $\text{C}_4\text{H}_5\text{Na}_2\text{N}_4\text{O 4aq}$ : deposited on adding alcohol to a strong solution of  $\text{NaOH}$  saturated with guanine. Confused efflorescent laminae, which rapidly absorb  $\text{CO}_2$  from the air. Decomposed by water.— $\text{C}_4\text{H}_5\text{Ba}_2\text{N}_4\text{O}$  (at  $110^\circ$ ): pointed prisms. Separates on cooling from a solution of guanine in baryta-water.— $\text{B'HgCl}_2\text{2aq}$ : obtained as a crystalline powder on adding cold saturated aqueous  $\text{HgCl}_2$  to a solution of guanine hydrochloride. V. sol. acids and  $\text{KCy aq.}$ — $\text{B'AgNO}_3$ : flocculent pp.; formed by mixing solutions of silver nitrate and guanine nitrate. Crystallises from hot  $\text{HNO}_3$  in slender needles (Strecker).

#### Reference.—BROMO-GUANINE.

GUANOLINE u. GUANTIDINE CARBOXYLIC ETHER.

**GUANYL-PHENYL-THIO-UREA**  $\text{C}_8\text{H}_8\text{N}_4$ , i.e.  $\text{NHPh.CS.NH.C(NH}_2)_2\text{NH}$  [176°]. Prepared by heating a mixture of phenyl-thiocarbimide (3 pts.), guanidine carbonate (2 pts.), and alcohol at  $100^\circ$  (Bamberger, B. 13, 1580; 14, 2638). Colourless monoclinic crystals. V. sol. alcohol. Alkaline in reaction. Slowly decomposed by boiling water into guanidine, phenyl thiocarbimide, aniline,  $\text{H}_2\text{S}$ , and  $\text{CO}_2$ . Boiling  $\text{HClAq}$ , forms guanidine, aniline,  $\text{H}_2\text{S}$ , and  $\text{CO}_2$ .

**Salts.**— $\text{B'HCl}$ : long glistening needles, more soluble in alcohol than in water; on boiling with water it evolves  $\text{H}_2\text{S}$ ;  $\text{CuSO}_4$  produces a violet pp. turning black on heating.— $\text{B'_1H}_2\text{SO}_4$ : \*pearly plates.— $\text{B'_1H}_2\text{C}_2\text{O}_4$ : \*white glistening scales.— $\text{B'_1C}_4\text{H}_5(\text{NO}_3)_2\text{OH}$ : yellow felted needles.

#### GUANYL-THIO-UREA $\text{C}_4\text{H}_5\text{N}_3\text{S}$ i.e.

$\text{SO}(\text{NH}_2)_2\text{NH.C(NH}_2)_2\text{NH}$ . *Thiodicyandiamidine*. White glistening prisms; m. sol. cold water.

**Formation.**—1. By digesting di-cyan-diamide with aqueous  $\text{H}_2\text{S}$  (Bamberger, B. 16, 1459).—2. By heating guanyl-urea with aqueous  $\text{H}_2\text{S}$  (B.).—3. From  $\text{CSCl}_2$  and thio-urea at  $110^\circ$ .—4. In small quantity by the action of  $\text{PCl}_5$  (1 mol.) on thio-urea (3 mols.) (Rathke, B. 11, 982).

**Reactions.**—Silver salts readily displace the S by O. On heating with ammoniacal  $\text{AgNO}_3$ , it is resolved into  $\text{H}_2\text{S}$  and di-cyan-diamide. When heated alone at  $100^\circ$  it changes to the isomeric guanidine sulphocyanide.

**Salts.**— $\text{B'_1H}_2\text{C}_2\text{O}_4\text{2aq}$ : sparingly soluble crystalline pp.— $\text{B'_1H}_2\text{SO}_4$ : \*white silky needles.— $\text{B'HCl}$ .

VOL. II.

#### GUANYL-UREA $\text{C}_4\text{H}_5\text{N}_3\text{O}$ i.e.

$\text{OO}(\text{NH}_2)_2\text{NH.C(NH}_2)_2\text{NH}$ . *Di-cyan-di-amidine*.

**Formation.**—1. By evaporating a solution of di-cyan-di-amide  $(\text{CN})_2(\text{NH}_2)_2$  in dilute  $\text{H}_2\text{SO}_4$  (Hasag, A. 122, 25), and is therefore also formed by the action of dilute  $\text{H}_2\text{SO}_4$  or  $\text{H}_3\text{PO}_4$  on cyanamide (Baumann, B. 6, 1874).—2. By fusing guanidine carbonate (1 pt.) with urea (2 pts.) (Baumann, B. 7, 446, 1768).—3. By heating a mixture of carbamic ether (2 pts.) and guanidine carbonate (1 pt.) at  $160^\circ$  as long as alcohol distils over (Bamberger, B. 20, 68).—4. A mixture of guanidine hydrochloride and potassium cyanate is heated at  $180^\circ$  (Bamberger).

**Preparation.**—The base, prepared by any of the above processes, is ppd. from the aqueous solution of the product by  $\text{CuSO}_4$  and  $\text{NaOH}$ . The resulting copper derivative is then decomposed by  $\text{H}_2\text{S}$ .

**Properties.**—Strongly alkaline crystals; absorbing  $\text{CO}_2$  from the air. V. sol. water and alcohol.  $\text{KClO}_4$  and  $\text{HCl}$  oxidise it to guanidine. Boiling baryta-water converts it into urea,  $\text{CO}_2$ , and  $\text{NH}_3$ . On evaporating a solution of guanyl-urea carbonate there is left guanidine carbonate,  $\text{NH}_3$ , and  $\text{CO}_2$  having been given off.

**Salts.**— $\text{B'HCl 4aq}$ : laminae, v. sol. water and alcohol.— $\text{B'_1H}_2\text{P}_2\text{Cl}_7$ : small orange crystals.— $\text{B'HNO}_3$ : needles.—Aurochloride: long golden needles.— $\text{B'_1H}_2\text{SO}_4\text{2aq}$ : long needles.— $\text{B'_1H}_2\text{C}_2\text{O}_4$ : crystalline powder. S. 67 at  $18^\circ$ .— $\text{B'_1H}_2\text{C}_2\text{O}_4$ .

**GUM.** This term is applied to carbohydrates, whether produced by plants or animals, which are amorphous, insoluble in alcohol, but form a sticky liquid with water, in which they either dissolve or swell up greatly. By nitric acid the vegetable gums are oxidised to mucic and oxalic acids. They give no colouration with iodine either before or after treatment with conc.  $\text{H}_2\text{SO}_4$ . Boiling dilute  $\text{H}_2\text{SO}_4$  converts them into glucose or a sugar  $\text{C}_6\text{H}_{12}\text{O}_6$ . Thus dextrose (glucose) is formed from lichenin; levulose is formed from levulin; galactose is formed from galactin, agar-agar, some kinds of gum arabic, and a gum in lucerne and other leguminous plants; while arabinose is formed from gum-arabic, cherry gum, gum tragacanth, and the gum in the cell walls of beet-root and poppies (Bauer, J. pr. [2] 80, 388). Gums are described under AGAR-AGAR, ARABIN, BASSORIN, CERASIN, DEXTRANS, DEXTRIN, GAMBOGE, GELOSE, GREVILLEA GUM, KAURI GUM, LACTOSIN, LEVULANE, LEVULIN, LICHENIN, MUCILAGE, PROTEIDS, Appendix Q, QUEBRACHO GUM, SHELLAC, SINISTRIN, TRITICIN.

**GUM AMMONIAC.** The dried sap of *Dorema ammoniacum*. It is partly soluble in water, but contains also an insoluble resin (Johnston, A. 44, 328; Hirschsohn, J. 1875, 869; Moss, J. 1878, 867). When fused with potash it gives resorcin and protocatechuic acid. The portion of gum ammoniac from Morocco soluble in alcohol gives by potash-fusion an acid  $\text{C}_{14}\text{H}_8\text{O}_6$ , which forms minute crystals, sl. sol. water, m. sol. alcohol, melting with decomposition at  $265^\circ$ , and giving with  $\text{FeCl}_3$  a violet colouration (Gold-schmidt, B. 11, 850).  $\text{HNO}_3$ , acting on gum ammoniac forms tri-nitro-resorcin. Distillation with zinc-dust forms *m*- and *p*-xylene, *m*-ethyltoluene,  $(2:1)\text{C}_6\text{H}_4\text{Et}(\text{OMe})$ , and a hydrocarbon  $\text{C}_{12}\text{H}_{18}$  ( $285^\circ$ ) which on oxidation with chromic

U U

mixture forms benzoic and acetic acids and resinous products (Giamician, *B.* 12, 1668; *G.* 9, 819).

**GUM, ANIMAL, v. PROTEIDS, Appendix C.**

**GUM ARABIC v. ARABIN.**

**GUM BENZOIN v. vol. i. p. 477.**

**GUM, BRITISH, v. DEXTRIN.**

**GUMMIC ACID**  $C_7H_6O_4$  (Reichardt). This name was applied by Fremy to arabin, but transferred by Reichardt (*A.* 127, 300) to an acid formed in the oxidation of glucose by Fehling's solution. Felsko (*A.* 149, 856; *Z.* [2] 5, 228), working under Reichardt's direction, gave the formula  $C_7H_6O_4$ , but according to Claus (*J. pr.* [2] 4, 63) gummic acid is more or less impure tartaric acid.

**Metagummic acid v. ARABIN and CERASIN.**

**GUM RESINS.** The hardened milky juice which exudes from incisions in the stem or roots of some plants. They are partly soluble in water (gum) and part of the residue is soluble in alcohol (resin). *Examples:* asafetida, aloes, galbanum, gamboge, gum ammoniac, myrrh, olibanum, opoponax, and scammony.

**GUM SENEAL v. ARABIN.**

**GUM COTTON v. CELLULOSE.**

**GUNPOWDER.** A mixture of charcoal, nitre, and sulphur, which when burnt produces large volumes of gases chiefly  $CO$ ,  $CO_2$ ,  $N$ ,  $H$ ,  $H_2S$ , and  $O$  (*v. DICTIONARY OF TECHNICAL CHEMISTRY*).

**GURJUN BALSAM v. WOOD OIL.**

**GURJUNIC ACID v. WOOD OIL.**

**GUTTA PERCHA.** A substance resembling caoutchouc obtained by boiling to dryness the milky sap which exudes from incisions in the bark of the *Ironandra Percha*, *Sapota Muelleri* (Bleekrode, *Rép. chim. app.* 1, 403), and *Bassia Parkii*.

Gutta percha is a brownish-red mass, S.G. .98. It is a very bad conductor of electricity. It softens at about  $48^\circ$ , but never possesses the elastic character of caoutchouc. It is deposited from its solution in  $CS_2$  in a very porous mass. Gutta percha is insol. water. It dissolves easily in benzene,  $CS_2$ , chloroform, and oil of turpentine. It is not attacked by solutions of  $HCl$ ,  $KOH$ , or  $HF$ . Hot conc.  $H_2SO_4$  carbonises it.  $HNO_3$  converts it into a yellow resin.

According to Payen (*C. R.* 85, 109) gutta percha, purified by solution in  $CS_2$ , consists of three hydrocarbons: 'gutta' a portion insoluble in boiling alcohol, amounting to 75 to 82 p.c.; 'alban' a portion soluble in boiling, but insoluble in cold, alcohol, amounting to 19 to 14 p.c.; and a yellow resin 'fluavil', soluble in cold alcohol, and amounting to 6 to 4 p.c. of the whole.

Gutta  $C_{10}H_{16}$ . Obtained by exhausting gutta percha with boiling alcohol and ether, dissolving the residue in chloroform, and ppg. by alcohol (Oudemans, *Rép. chim. app.* 1, 455; Von Baumhauer, *J. pr.* 73, 277; Adriani, *Z.* 1860, 496; Hofmann, *J.* 115, 297). 'White powder,

cakes together and becomes transparent at  $10^\circ$  begins to melt at  $150^\circ$ ; at  $180^\circ$  an oil distils over, and at  $280^\circ$  it froths strongly. It is insol. alcohol and ether, sol. cold chloroform and  $CS_2$  sol. hot benzene and oil of turpentine. After exposure to the air it becomes soluble in ether. Gutta is strongly attacked by ozonised oxygen. Conc.  $HClAq$  attacks it, apparently forming compounds containing chlorine. On dry distillation it behaves like caoutchouc, giving isoprene  $C_5H_8$  caoutchene  $C_{10}H_{16}$ , heveene (Greville William *C. J.* 15, 124), and a volatile acid. When exposed to air and light, especially at  $25^\circ$  to  $30^\circ$  it is completely deprived of flexibility through oxidation (Hofmann, *C. J.* 18, 87; Adriani, *C. J.* 2, 227, 289, 313). Gutta percha may be kept for a long time unchanged under water or in the dark (W. A. Miller, *C. J.* [3] 3, 273).

**Alban.** White crystalline resin; best obtained by extracting gutta percha with ether and boiling the resulting extract with alcohol to remove fluavil. Begins to melt at  $100^\circ$ , and is perfectly fluid and transparent at  $180^\circ$ . Insol. water, alkalis, and acids; v. sol. oil of turpentine, benzene,  $CS_2$ , ether, chloroform, and hot alcohol (Payen, *C. R.* 35, 109). According to Oudemans (*Rép. chim. app.* 1, 455) alban from Indian gutta percha may be represented by the formula  $C_{10}H_{16}O$ , and at  $130^\circ$  by  $C_{10}H_{16}O$ , and melts at  $140^\circ$ ; S. (alcohol) .61 in the cold; .54 at  $78^\circ$ .

**Fluavil**  $C_{10}H_{16}O$  [42°] (Oudemans). Yellow resin; sol. alcohol, ether, benzene, oil of turpentine,  $CS_2$ , and chloroform, remaining as an amorphous mass when these solutions are evaporated. Conc.  $HClAq$  dissolves it without decomposition.

Gutta percha from *Bassia Parkii* resembles ordinary gutta percha in its physical properties and has S.G. .976. It is much less soluble in light petroleum, ether,  $HOAc$ , and oil of turpentine, but is equally soluble in  $CS_2$ , chloroform, and benzene. It consists of gutta (91.5 p.c.) alban (6 p.c.), and fluavil (2.5 p.c.) (Heckel & Schlagdenhauffen, *C. R.* 101, 1069).

**GYROPHORIC ACID**  $C_{10}H_{16}O_4$ . An acid obtained from two lichens, *Gyrophora pustulata* and *Lecanora tartarea*, collected in Norway for the manufacture of archil. The lichen is macerated with milk of lime, and the filtrate ppg. by  $HCl$ ; the pp. is dissolved in boiling alcohol, containing animal charcoal, from which the acid crystallises on cooling (Stenhouse, *P. T.* 1849, 393). Small soft crystals; nearly insol. water, v. sl. sol. ether and cold alcohol, m. sol. boiling alcohol. Its solutions do not redden litmus. Boiling aqueous  $KOH$  or baryta resolve it into  $CO_2$  and orcin. Bleaching-powder reddens its solution. When mixed with  $NH_3$  and exposed to the air it forms a purple substance. Boiling alcohol forms orsellin ether. Gerhardt (*Traité*, 3, 818) regarded gyrophoric acid as identical with lecanoric or evernic acid.

# H

**HÆMATEIN** v. **HEMATOXYLIN**.

**HÆMATIN** v. **HÆMOGLOBIN**.

**HÆMATO-CRYSTALLIN** v. **HÆMOGLOBIN**.

**HÆMATO-GLOBULIN** v. **HÆMOGLOBIN**.

**HÆMATOIDIN** v. **HÆMOGLOBIN**.

**HÆMATOIN** v. **HÆMOGLOBIN**.

**HÆMATOLIN** v. **HÆMOGLOBIN**.

**HÆMATO-PORPHYRIN** v. **HÆMOGLOBIN**.

**HÆMATO-PORPHYROIDIN** v. **HÆMOGLOBIN**.

**HÆMATOXYLIN**  $C_{16}H_{10}O_6$ . *Hæmatin*. A colourless crystalline substance from which the colouring matter of logwood (*Hæmatoxylin campechianum*) is derived (Chevreul, *A. Ch.* [2] 80, 128; 82, 53, 126; Gollfer-Besseyre, *A. Ch.* [2] 70, 272; Erdmann, *A.* 44, 232; Hesse, *J. pr.* 75, 216; *A.* 109, 332). Prepared by leaving the commercial extract of logwood, previously mixed with sand, in contact with five times its volume of wet ether for several days, with frequent shaking; the extract is evaporated, and the residue recrystallised from water containing a little ammonium sulphite. Dimetric crystals (containing 3aq). When a supersaturated solution is allowed to stand in the cold it deposits hemihedral trimetric crystals (containing aq). The monohydrate is also obtained in granular crystals by pouring a solution that has been saturated at 100° into a cold vessel containing a small quantity of a solution of acid ammonium sulphite. Hæmatoxylin is sl. sol. cold water, v. sol. alcohol and ether. It dissolves in a saturated solution of borax more easily than in pure water, the solution being neutral or slightly acid, and exhibiting a bluish fluorescence. Alcohol does not ppt. borax from this solution. From the solution in borax the hæmatoxylin is ppd. by acids in the monohydrated form, and by salts (e.g. NaCl, KCl, NH<sub>4</sub>Cl, K<sub>2</sub>FeCy<sub>6</sub>, and HNH<sub>4</sub>SO<sub>4</sub>) as an amorphous mass. Hæmatoxylin dissolves in warm Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> forming a purple liquid from which it is deposited on cooling in the amorphous form. It also dissolves freely in Na<sub>2</sub>HPO<sub>4</sub>, the solution remaining alkaline. Hæmatoxylin has a sweet taste, resembling liquorice. Its solutions are dextrorotatory,  $[\alpha]_D^{20} = +92.5^\circ$  in a 1 p.c. solution. It reduces Fehling's solution and ammoniacal AgNO<sub>3</sub> in the cold. An aqueous solution of hæmatoxylin is not altered by contact with pure air or oxygen, but, if the slightest trace of ammonia be present, the liquid acquires a red colour due to hæmatein (v. *infra*). Thus if the solution is boiled in a glass vessel it becomes purple by dissolving alkali from the glass (Maschke, *B.* 7, 1635; *Ar. Ph.* [3] 6, 34; Mitchell, *Am. Ch.* 6, 91). HNO<sub>3</sub> oxidises it at first to hæmatein, but ultimately to oxalic acid. H<sub>2</sub>SO<sub>4</sub> and HCl have but little action on it. Hæmatoxylin dissolves in alkalis and alkaline carbonates forming a purple solution, the colour being destroyed by acids (Wildenstein, *Fr.* 2, 9). Baryta-water added to a solution of hæmatoxylin freed from air by boiling forms a white pp. which turns blue if exposed to air. Basic and normal lead acetates give a white pp. turned blue in air; cupric ace-

tate gives a greenish-grey pp. which soon becomes dark-blue with a coppery lustre. SnCl<sub>4</sub> gives a rose-coloured pp. Alum colours the solution red but gives no pp. BaCl<sub>2</sub> colours the liquid red, and then forms a red pp. AuCl<sub>3</sub> is reduced by hæmatoxylin. Ammonium vanadate gives a blue-black colour (Wagner, *D. P. J.* 223, 631). According to Schützenberger a. Paraf (*Z.* 1862, 42) the violet solution of hæmatoxylin in ammonia may be decolourised by heating for 48 hours at 100° in an exhausted tube; the colourless product, called 'hæmatinamide' is re-oxidised on exposure to air, becoming violet. Resorcin and pyrogallol are among the products of the dry distillation of hæmatoxylin (R. Meyer, *B.* 12, 1392). Potash-fusion gives pyrogallol and formic acid (Erdmann a. Schultz, *A.* 216, 240). Sodium-amalgam or zinc and dilute H<sub>2</sub>SO<sub>4</sub> do not reduce hæmatoxylin (Reim, *B.* 4, 329). Chlorine, bromine, PCl<sub>5</sub>, and HI yield resinous products. According to Frébaul (*J. Ph.* [4] 23, 338) the red colour of alkaline solutions of hæmatoxylin is destroyed by iodine.

*Penta-acetyl derivative*  $C_{16}H_5Ac_5O_6$ . [166°]. From hæmatoxylin and AcCl (Erdmann a. Schultz, *A.* 216, 232; cf. Reim, *B.* 4, 331). Silky crystalline tufts; becomes coloured in moist air.

*Bromo-hæmatoxylin*  $C_{16}H_9BrO_6$ . Dissolves in aqueous KOH or NaOH with a blue colour, in aqueous NH<sub>3</sub> with a red colour.

*Pent-acetyl derivative*  $C_{16}H_5BrO_6Ac_5$ . [210°]; fine colourless needles; sol. alcohol, acetic acid, benzene and chloroform. Formed by adding bromine to a cold acetic acid solution of penta-acetyl-hæmatoxylin (Buchka, *B.* 17, 683).

*Di-bromo-hæmatoxylin*  $C_{16}H_7Br_2O_6$ . From hæmatoxylin and Br in HOAc (Dralle, *B.* 17, 373). Deep-red needles. Decomposes above 120°. Its aqueous solution is brownish-red.

*Penta-acetyl derivative*  $C_{16}H_5Br_2O_6Ac_5$ . From penta-acetyl-hæmatoxylin and Br in HOAc at 110° (D.). Crystals; decomposes above 180° without melting.

*Hæmatoxylin-phthaléin*  $C_{26}H_{14}O_{10}$ . Prepared by heating hæmatoxylin with phthalic anhydride (Letts, *B.* 12, 1651). Brown amorphous mass, insol. water, sol. alkalis, forming a purple-red solution.

*Hæmatein*  $C_{16}H_{10}O_6$ . S. .06 at 20°; S. (ether) .018 at 20°.

*Preparation*.—Extract of logwood is dissolved in hot water and, after cooling, NH<sub>3</sub> in slight excess is added. The solution is exposed to air which changes hæmatoxylin to hæmatein, the ammonia compound of which is ppd. This pp. (40g.) is dissolved in hot water (1000g.) containing acetic acid (300 c.c.), and the solution is filtered. On cooling crystals of hæmatein appear (Hummel a. A. G. Perkin, *C. J.* 41, 387; cf. Halberstadt a. Reis, *C. J.* 41, 868; *B.* 14, 611).

*Properties*.—Microscopic reddish-brown plates with yellowish-green lustre. Sparingly soluble in water, alcohol, ether, and acetic acid.

Forms with  $\text{NH}_3$  a brown-violet solution, with conc.  $\text{NaOH}$  a purple-blue solution; in air these liquids turn red and finally brown. Freely soluble in conc.  $\text{HClAq}$ . It dissolves in alkaline bisulphites, and is reppd. by hot dilute  $\text{H}_2\text{SO}_4$ .

**Reactions.**—1. Cold conc.  $\text{H}_2\text{SO}_4$  dissolves it. On pouring the solution into water a reddish-brown pp. of altered hæmatein is formed. On adding glacial acetic acid to the solution in cold conc.  $\text{H}_2\text{SO}_4$ , an orange crystalline powder iso-hæmatein sulphate,  $\text{C}_{18}\text{H}_{11}\text{O}_5\text{SO}_3\text{H}$ , is ppd. This body is converted by dilute (80 p.c.) alcohol into lustrous orange-red crystals of  $(\text{C}_{18}\text{H}_{12}\text{O}_5)_2\text{C}_{18}\text{H}_{11}\text{O}_5\text{SO}_3\text{H}$ .—2. With  $\text{HCl}$  at  $100^\circ$  it forms orange-red needles of iso-hæmatein-chlorhydrin  $\text{C}_{18}\text{H}_{11}\text{O}_5\text{Cl}$ , soluble in water with decomposition and separation of  $\text{HCl}$ . Its solution is orange. With alcoholic  $\text{KOH}$  it gives a reddish-violet solution. Conc.  $\text{H}_2\text{SO}_4$  converts it into iso-hæmatein sulphate.—3. With  $\text{HBr}$  it gives a corresponding bromhydrin,  $\text{C}_{18}\text{H}_{11}\text{O}_5\text{Br}$ .—4. Decolourised by  $\text{Zn}$  and dilute  $\text{H}_2\text{SO}_4$ , but not reduced to hæmatoxylin thereby. Boiling aqueous  $\text{SO}_2$  behaves in like manner (Reim).—5.  $\text{AcCl}$  gives no acetyl derivative.

**Ammonium derivative**  $\text{C}_{18}\text{H}_{10}(\text{NH}_4)_2\text{O}_5$ : violet-black grains; forming a purple solution in water, and a brownish-red solution in alcohol, gives off  $\text{NH}_3$  over  $\text{H}_2\text{SO}_4$ .

**Iso-hæmatein**  $\text{C}_{18}\text{H}_{10}\text{O}_5$ . A solution of the chlorhydrin  $\text{C}_{18}\text{H}_{11}\text{O}_5\text{Cl}$  gives with  $\text{Ag}_2\text{O}$  a solution which, on evaporating, leaves amorphous iso-hæmatein with green lustre.

**Properties.**—Solution in  $\text{NaOH}$  is red-violet, in  $\text{NH}_3$  is dull red-purple; with ammoniac sulphide a red-purple pp. is got (hæmatein is nearly decolourised by this reagent). Lead acetate gives a red-purple pp.

**Iso-hæmatein** compounds dye with alumina chocolate-red, with iron, slate to black. The colours are faster than those of hæmatein. The generation of iso-hæmatein in place of ordinary hæmatein from  $\text{C}_{18}\text{H}_{11}\text{O}_5\text{Cl}$  is peculiar. Perhaps it is  $(\text{C}_{18}\text{H}_{11}\text{O}_5)_2$ , as indicated by the sulphate.

**( $\beta$ )-Hæmatein**  $\text{C}_{18}\text{H}_{10}\text{O}_5$  3aq. Deposited as small brownish-red tufts from an ethereal solution of hæmatoxylin to which a few drops of  $\text{HNO}_3$  have been added (Reim, B. 4, 531). It is more soluble in boiling water than hæmatein (Erdmann & Schultz, A. 216, 236). It is reconverted into hæmatoxylin by boiling with aqueous  $\text{SO}_2$ , or with zinc and dilute  $\text{H}_2\text{SO}_4$ .  $\text{AcCl}$  gives an acetyl derivative [ $216^\circ$ - $219^\circ$ ].

**HÆMIN** v. HÆMOGLOBIN.

**HÆMOCHROMOGEN** v. HÆMOGLOBIN.

**HÆMOCYANIN** v. PROTEIDS.

**HÆMOGLOBIN** (syn. *Hæmato-globulin*, *hæmato-crystallin*). This pigment composes from 86-90 per cent. of the solid constituents of the red blood corpuscles of vertebrates; it is also found in the blood plasma of many invertebrate animals, and in the red corpuscles of the hæmo-lymph of a few invertebrates (Lankester). For a complete list of the animals in the blood of which it has been described v. Halliburton (*J. Physiol.* 6, 332). It is found in the muscle-plasma of most animals, even when none occurs in the blood, as in some invertebrates (Lankester, *Pflüger's Archiv*, 4, 315); it is most abundant in the red muscles of rodents. It is also found

in the nerve-cells of *Aphrodite aculeata* (Gamgee, *Physiol. Chem.* 420).

**Preparation.**—Leidig (*Zeits. f. wiss. Zool.* 1, 116), Reichert (*Müller's Archiv*, 1849, 197), Kölliker (*Zeits. f. wiss. Zool.* 1, 216) first observed that blood from different sources deposited crystals of a red colour. Funke (*Zeit. f. rat. Med.* N. F. 1, 184; 2, 204, 288) recognised that they consisted of the red pigment of the blood. Lehmann (*Sitz. W.* 40, 65), Lang (*ibid.*), and Præyer (*Die Blutkristalle*, Jena, 1871) have also worked at the subject. The principal methods for preparing these crystals will be found in detail in Gamgee's *Physiol. Chem.* 85-88. The crystals may be obtained with ease from the blood of some animals (rat, guinea pig) by simply adding water to the blood; this first dissolves the hæmogoblin from the corpuscles, and without further treatment the crystals form in a few minutes. A very excellent method consists in adding to the defibrinated blood one-sixteenth of its volume of ether, or a mixture of alcohol and ether; on shaking the mixture the corpuscles dissolve, forming a lake-coloured fluid, and in a period varying in different animals from a few minutes to three days, a thick magma of crystals is formed, which may be purified by washing with 25 p.c. alcohol, and by re-crystallisation. In other methods the corpuscles are broken up by repeatedly freezing and thawing the blood with or without the previous addition of a quarter of its volume of alcohol, and crystals are thus obtained. The blood of the mouse is said to crystallise when drawn, without any further treatment; in septic diseases in man, or by adding putrid serum to the blood, there is the same crystalline tendency (C. J. Bond, *Lancet*, Sept. 10 and 17, 1897). The crystals obtained by all these methods are microscopic; larger crystals are formed by sealing blood which has stood in the air for twenty-four hours in narrow glass tubes, and keeping them for some days at  $37^\circ\text{C}$ . On then emptying their contents into watch glasses the crystals form (Gschleiden, *Physiol. Methodik*, 361). For microscopical investigation a very convenient method is to mount a drop of blood in Canada balsam, and the crystals separate in a few minutes (Stein, *Virchow's Archiv*, 97, 493). The crystals in all these cases are generally spoken of as hæmoglobin crystals; it would be more correct to speak of them as crystals of oxy-hæmoglobin, the loose combination of oxygen and hæmoglobin that exists in arterial blood. Crystals of pure or venous hæmoglobin have, however, been obtained by Hüfner and by Nencki and Sieber (*Chem. Soc. Abst.* 1886, p. 482).

**Crystalline form.**—Not only does the hæmoglobin of different animals differ in the readiness with which it crystallises, and in its solubility in water, but also in crystalline form. As obtained from the majority of animals, the crystals are prisms or plates belonging to the rhombic system; the exceptions to this rule are the guinea-pig, in which the crystals were at first supposed to be regular tetrahedra (Kunde, *Zeits. für rat. Med.* N. F. 2, 276), but have since been shown by Von Lang to be rhombic tetrahedra. In birds the crystals are often tetrahedral. These crystals are doubly refracting and pleochromatic. In three animals, the

squirrel (Kunde), hamster (Preyer), and mouse (Bojanowski), six-sided plates have been described. The statement regarding mouse's crystals is, however, erroneous. Rhombohedra have been obtained from hamster's blood. Occasionally six-sided plates are obtained from rat's blood (Halliburton, *Quart. Jour. Mic. Sci.* 1887, 190). These crystals, if they are lying flat, appear dark between crossed nicols, and therefore belong to the hexagonal system. The amount of water of crystallisation varies greatly in the crystals from different sources, and it is probably owing to this that the difference in crystalline form is due (Hoppe-Seyler, *Physiol. Chem.* 377; C. Bohr, *Untersuch. über d. Sauerstoffaufnahme des Blutfarbstoffes*, Kopenhagen, 1885; Halliburton, *l.c.*).

**Composition.**—Hæmoglobin differs from most of the other proximate constituents of the body in containing iron. Preyer's formula for it is  $C_{600}H_{900}N_{12}FeS_2O_{170}$ . Determinations of the sulphur by other observers were, however, contradictory; on this ground Lehmann and others advanced the theory that hæmoglobin is not a chemical unit, but consists of a colouring matter, hæmatin, which contains the iron, mechanically mixed with a crystallised proteid. A seeming confirmation of this theory was advanced by Struve (*Zeit. Prakt. Chem.* 1884), who extracted hæmatin from the crystals by alcoholic ammonia, leaving them colourless. Zinoffsky (*Zeit. Physiol. Chem.* 10, 16) points out, however, that alcoholic ammonia is a powerful reagent, and shows that the conflicting results as to the quantity of sulphur present are due to bad methods of preparation of the hæmoglobin. Adopting the ether method of preparing the crystals (for the modifications of the method as already described the original paper must be consulted), he found that the empirical formula for hæmoglobin is  $C_{712}H_{1132}N_{212}S_2FeO_{245}$ . By heat, or by the action of strong acids or alkalis, hæmoglobin is decomposed into hæmatin ( $C_{48}H_{72}N_8FeO_{40}$ ) and a proteid or mixture of proteids known under the name Globin (for the properties of globin v. proteins).

**Properties.**—Though crystallisable, hæmoglobin is not diffusible; its colour differs with the amount of oxygen with which it is combined; the pure pigment has a purplish tinge; the oxygenated condition in which it usually exists is a yellowish-red. In both conditions solutions of the pigment show with the spectroscopic typical absorption bands. The spectrum of oxyhæmoglobin varies with the concentration of the solution; in addition to a certain amount of absorption of both ends of the spectrum there are two typical bands between the  $\nu$  and  $\alpha$  lines, the  $\alpha$  band has for its centre the wave-length 573; the  $\beta$  band, which is wider and less well-defined, has its centre at wave-length 558 (Hoppe-Seyler) (see spectrum, 2). Stokes first showed that on the addition of reducing agents to such a solution the colour of the liquid changes to that of hæmoglobin, and this has only one absorption band, which occupies approximately the light space between the two bands of oxyhæmoglobin (see spectrum, 3). The most convenient reducing agent to use is 'Stokes's reagent,' which must always be freshly prepared by adding a small quantity of citric or tartaric acid to a

solution of ferrous sulphate, and then ammonia till the reaction is alkaline. Or a solution of ammonium sulphide, or a stream of a neutral gas like hydrogen may be used. If the solution which shows the spectrum of reduced hæmoglobin be agitated with the air or oxygen it once more becomes brighter in colour, and shows the two bands of oxyhæmoglobin. This spectroscopic test is the one most usually applied for the identification of hæmoglobin. The bands are still perceptible when the solution contains only 1 part of hæmoglobin in 10,000 of water. Another test frequently used is to obtain crystals of hæmin (*q. v.*). The crystals of oxyhæmoglobin dried *in vacuo* still retain 3.4 per cent. of water of crystallisation, which is driven off by heating to 110°–120°C. The dried substance may be heated to 100°C. without undergoing decomposition.

Hæmoglobin gives all the tests of proteins. Oxyhæmoglobin has the power of decomposing hydrogen peroxide. Preyer finds that 1 grm. of hæmoglobin can link to itself 1.67 c.c. of respiratory oxygen; Hüfner (*Zeit. physiol. Chem.* i. 317) gives approximately the same figure; the theory of A. Schmidt that hæmoglobin has the power of oxidising the oxygen it thus links to itself has been disproved by Pfüger (*Pfüger's Archiv*, 10, 252).

**Estimation of hæmoglobin.**—(a) *From the amount of iron;* dry hæmoglobin contains 0.42 p.c. of iron. A weighed quantity of blood is calcined; the ash is exhausted with hydrochloric acid to obtain ferric chloride, which is transformed into ferrous chloride, and titrated with potassium permanganate. (b) *Colorimetrically* (Hoppe-Seyler; Rajewsky; Malassez); the most convenient instrument is Gower's hæmoglobino-meter (*Lancet*, vol. ii. 1873, p. 822). (c) *Spectroscopically*, by comparing the amount of absorption of light with that of a standard solution (*v. Hüfner, l.c.*, Preyer, *l.c.* On the Spectrophotometer, v. S. Lea, *J. Physiol.* 5, 289). The absorption coefficient of oxyhæmoglobin increases each time it is recrystallised (F. Krüger, *Zeit. Biol.* 24, 471). *V. also* Fleischl, *Maly's Jahrb.* xv. 149; Otto, *ibid.* 146; Quinquaud and Brany, *ibid.* 151; E. Lambing, *Arch. de Physiol.* [4] 12, 1.

**Compounds.**—**Oxyhæmoglobin.** This loose combination of oxygen and hæmoglobin is formed in the pulmonary or branchial capillaries, and forms the oxygen carrier to the tissues to which it goes, and where it parts with its oxygen, returning in the venous blood for a fresh supply. As already stated, this compound can also be made artificially from hæmoglobin when in solution outside the body. For the most recent work regarding the dissociation of oxyhæmoglobin v. Hüfner, *Zeit. physiol. Chem.* 12, 568; 13, 285. Carbonic oxide hæmoglobin is formed when carbonic oxide is breathed instead of, or mixed in undue proportions with, oxygen. The formation of this substance is the cause of death in poisoning from this gas, which is contained, for instance, in the fumes of burning charcoal. The compound has a bright cherry-red colour, is much more stable than oxyhæmoglobin. Its absorption bands are very like those of oxyhæmoglobin, but they are situated rather nearer to the blue end of the spectrum (see spectrum, 4).

the addition of reducing agents does not cause any reduction to the condition of hæmoglobin. It can be obtained in a crystalline condition, and the crystals are of the same form as those of oxyhæmoglobin, but are more stable. For other tests for CO hæmoglobin v. Hoppe-Seyler (*Zeit. physiol. Chem.* 2, 131), Salkowski (*ibid.* 12, 227), Katayama (*Virch. Arch.*, 1888, p. 53). Nitric oxide hæmoglobin forms similar crystals, and in solution has an absorption spectrum resembling those of the two preceding substances. These three compounds are isomorphous, one molecule of each gas being replaceable by one of either of the other two, and is presumably linked with one molecule of hæmoglobin. Compounds of hæmoglobin with acetylene and with hydrocyanic acid have been also described (Hoppe-Seyler, *Med. Chem. Unters.* 2, 207).

**Methæmoglobin.** This is occasionally found in the body; e.g. in sanguineous effusions and in the urine. Our chief knowledge of it is, however, obtained from preparations of it from hæmoglobin made artificially. By simply allowing blood to stand for some days it turns acid, and of a brownish tint, and its hæmoglobin is found to be wholly or partially transformed into methæmoglobin. It may also be obtained by adding oxidising agents to blood, or to solutions of oxyhæmoglobin or hæmoglobin, e.g. potassium permanganate, potassium ferricyanide, nitrites, &c. (for a list of such substances v. G. Hayem, *Compt. Rend.* 102, 698). On the subsequent addition of reducing agents, first oxyhæmoglobin and then hæmoglobin is again formed. This is seen best by spectroscopic examination. The reduction, however, cannot be effected by simple mechanical means like a vacuum or a stream of hydrogen. The typical band of methæmoglobin is situated in the red between the c and d lines, rather nearer to the former (see spectrum, 5); in a dilute solution three other bands are seen (see spectrum, 6). Methæmoglobin may also be obtained in a crystalline form (guinea-pig, tetrahedra; rat, squirrel, horse occasionally, hexagonal; in most other animals, rhombic). A ready method of obtaining these crystals for microscopic examination is by shaking a few drops of amyl nitrite with a few c.c. of defibrinated blood, and then on mounting on a slide a drop of the mahogany-coloured mixture that results, crystals appear in a few minutes (Halliburton, *Quart. J. of Mic. Sci.* 1887, 201). Other methods consist in adding a nitrite and alcohol, and freezing (Gamble, *Phil. Trans.* 1868, 589, where they are described, however, as a compound of hæmoglobin with nitrous acid), or ferricyanide of potassium may be used instead (Hüfner, *Zeit. Physiol. Chem.* 8, 366). Sorby considered methæmoglobin as a peroxyhæmoglobin (*Quart. J. Mic Sci.* 1870, 400). Hoppe-Seyler on the contrary believed that it was a suboxyhæmoglobin, intermediate between oxyhæmoglobin and hæmoglobin, but that the oxygen was more firmly combined than it is in oxyhæmoglobin; he found by removing some of the oxygen from oxyhæmoglobin by means of an air-pump, or by nascent hydrogen, that methæmoglobin was formed (*Zeit. Physiol. Chem.* 2, 150). Hüfner and Küls (*ibid.* vol. vii.), having been able to obtain pure crystallised methæmoglobin, have found that the oxygen in both that compound

and in oxyhæmoglobin are equal in amount but combined more feebly in the latter.

**Parahæmoglobin.**—This was described by Nencki and Sieber (*Arch. Exper. Path. u. Pharmacol.* 10, 331; *Ber.* 18, 2126) as a special compound; but is regarded by Hoppe-Seyler (*Zeit. Physiol. Chem.* 10, 331) as a coagulation product brought about by the action of alcohol

#### DERIVATIVES OF HÆMOGLOBIN.

**Hæmatin** ( $C_{24}H_{16}N_8Fe_2O_{10}$ ) is the brown pigment obtained by the action of acids or alkalis on hæmoglobin in the presence of oxygen. This decomposition occurs more readily in the hæmoglobin of some animals (dog, man, &c.) than in others (herbivora) (Krüger, *Zeit. Biol.* 24, 318). It may be obtained by adding acetic acid to blood, and then extracting the hæmatin with ether. Mac-Munn recommends the following method: blood clot is extracted with rectified spirit containing sulphuric acid (1 in 17); the extract is filtered and agitated with chloroform, which assumes a reddish-brown colour and is separated, filtered, and washed with water to remove the acid. On evaporating the chloroform the hæmatin is obtained as a bluish-black powder (*J. Physiol.* 6, 22). Hoppe-Seyler obtains hæmatin from hæmin, which is first dissolved in solution of potassium hydrate, and the hæmatin prod. by hydrochloric acid (*Med. Chem. Unters.* 4, 623). Hæmatin dissolved in an acid solution shows four absorption bands (4 banded hæmatin or hæmatoin); first, one between the c and d lines, this is the most distinct and is nearer to the c line than the corresponding band of methæmoglobin; secondly, a faint narrow band close to d; thirdly, two much broader bands, one between d and e and another between e and f (see spectrum, 7). When hæmatin is dissolved in an alkaline solution (alkaline hæmatin) one band only is seen, viz. a faint shading on the red side of the d line (see spectrum, 8). There is, however, a large absorption of the violet end of the spectrum. On adding reducing agents to alkaline hæmatin, the bands of reduced hæmatin (hæmochromogen) are seen.

Hæmatin is insol. water, ether, alcohol, and dilute acids; v. sol. solutions of caustic alkalis, and hot alcohol holding sulphuric acid in solution. It can be heated to 180° without undergoing decomposition; at a temperature above this it burns and evolves hydrocyanic acid, and leaves an ash of oxide of iron amounting to 12.6 p.c.

**Hæmochromogen** ( $C_{24}H_{14}N_8FeO_9$ ). When hæmoglobin is decomposed in the absence of oxygen, instead of hæmatin, a substance of a purple colour called hæmochromogen is produced, which is converted into hæmatin in contact with oxygen. A solution of oxyhæmoglobin is freed from oxygen by a stream of hydrogen, and then mixed with an alcoholic solution of sulphuric acid or caustic potash (Hoppe-Seyler, *Med. Chem. Unters.* 4, 528, 377; *Zeit. physiol. Chem.* 1, 139). This substance is identical with the reduced hæmatin of Stokes, obtained by adding a reducing agent like ammonium sulphide to alkaline hæmatin in the presence of proteids (Jäderholm, *Maly's Jahrb.* 6, 85; Linossier, *C. R.* 104, 1296). Hæmochromogen shows two absorption bands, one midway between the d

and  $\pi$  lines, and the other occupying the space between  $\pi$  and  $\delta$  (see spectrum, 9). In testing for blood where the hæmoglobin has undergone decomposition, as in old stains, the most readily obtained spectrum is that of hæmochromogen. The stained fabric is extracted with a little caustic alkali, and ammonium sulphide or hypsulphite of soda added; the two bands of hæmo-

immediately below  $\nu$ , and another nearly intermediate between  $\nu$  and  $\pi$  (see spectrum, 10). The alkaline solution has four bands: one between  $\sigma$  and  $\nu$ , two between  $\nu$  and  $\pi$ , and a fourth, which extends through  $\frac{1}{2}$  of the space between  $\delta$  and  $\pi$  (see spectrum, 11). A second iron-free derivative has been obtained from hæmatin by Hoppe-Seyler; he calls it *hæmatolin* ( $C_{16}H_{12}N_4O_4$ ), it

1. Solar spectrum.
2. Spectrum of oxyhæmoglobin (0.37 p.c. solution). First band,  $\lambda$  589-564; second band, 555-517.
3. Spectrum of hæmoglobin. Band,  $\lambda$  597-535.
4. Spectrum of CO hæmoglobin. First band,  $\lambda$  583-564; second band, 547-521.
5. Spectrum of methæmoglobin (concentrated solution). First band,  $\lambda$  647-622; second band,  $\lambda$  587-571; third band,  $\lambda$  532; fourth band,  $\lambda$  514-490.
6. Spectrum of methæmoglobin (dilute solution). First band,  $\lambda$  647-622; second band,  $\lambda$  587-571; third band,  $\lambda$  532; fourth band,  $\lambda$  514-490.
7. Spectrum of acid hæmatin (etheral solution). First band,  $\lambda$  656-615; second band,  $\lambda$  597-577; third band,  $\lambda$  557-539; fourth band,  $\lambda$  517-488.
8. Spectrum of alkaline hæmatin. Band from  $\lambda$  630-562.
9. Spectrum of hæmochromogen (reduced hæmatin). First band,  $\lambda$  569-542; second band,  $\lambda$  535-504.
10. Spectrum of acid hæmatoporphyrin. First band,  $\lambda$  607-593; second band,  $\lambda$  585-536.
11. Spectrum of alkaline hæmatoporphyrin. First band,  $\lambda$  633-612; second band,  $\lambda$  589-564; third band,  $\lambda$  549-529; fourth band,  $\lambda$  513-488.

The above measurements (after MacMunn) are in millionths of a millimetre. The liquid was examined in a layer one centimetre thick. The edges of ill-defined bands vary a good deal with the concentration of the solution.

chromogen or in weak solutions the better marked band (that between  $\nu$  and  $\pi$ ) then appear.

**Hæmatoporphyrin** ( $C_{16}H_{12}N_4O_4$ ). This pigment is obtained by adding blood or pure hæmatin to conc. sulphuric or hydrochloric acid; the action of the acid is to remove the whole of the iron in the condition of a ferrous salt. It can be ppd. by adding water to this compound. The pp. is soluble in water and in alkaline leys. The acid solution exhibits spectroscopically one band

is nearly insoluble in sulphuric acid and caustic alkalis. Various derivatives of hæmatoporphyrin (hæmatoporphyrinidin, isohæmatoporphyrin, &c.) are described by Nobel (C. C. 1887, 538). Hæmatoporphyrin occurs as a natural pigment in many invertebrates; e.g. in the dorsal streak of the earth-worm. It is probably derived here not from hæmoglobin, but from histohæmatins which occur in these animals, and which yield many of the decomposition products

of hæmoglobin (MacMunn, *J. Physiol.* 8, 384). A derivative called uro-hæmatoporphyrin may occur in morbid human urine (MacMunn, *J. Physiol.* 10, 71).

**Hæmin.** *Hydrochloride of Hæmatin.* This is obtained for microscopical examination by boiling blood with glacial acetic acid and a crystal of sodium chloride (fresh blood contains, however, sufficient sodium chloride) on a slide; on cooling, rhombic crystals of a dark-brown colour separate (Teichmann); this is one of the best tests for blood. It has been prepared on a large scale by Hoppe-Seyler, who ascribes to it the formula  $C_{44}H_{36}N_4FeO_{10} \cdot 2HCl$ . Similar crystalline compounds are obtainable in which hydrobromic and hydriodic acids respectively take the place of HCl in the above formula (V. D. Harris, *Brit. Med. J.* 1886, 2, 103). Nencki & Sieber (*Ber.* 17, 2267; 18, 392; *Monatschr.* 9, 115; *Arch. f. exp. Path. und Pharmac.* 24) ascribe to hæmatin the formula  $C_{44}H_{36}N_4FeO_{10}$ ; and say hæmin crystals are composed of the hydrochloride of its anhydride  $C_{44}H_{36}N_4FeO_{10} \cdot HCl$ . Their formula for hæmatoporphyrin is  $C_{52}H_{40}N_4O_8$ . Of this they describe an anhydride and a crystalline hydrochloride. It is isomeric with bilirubin.

**Cyan-hæmatin.** A compound with this name is said to be formed when potassium cyanide is added to an ammoniacal solution of pure hæmatin. It exhibits spectroscopically one band extending from  $\nu$  and  $\epsilon$ , and split into two by reducing agents.

**Nitric oxide Hæmatin.**—This is produced by passing nitric oxide into an alcoholic solution of hæmatin. Its absorption bands resemble those of oxyhæmoglobin (Linossier, *C. R.* 104, 1296).

**Hæmatoidin.** Everard Home (*A Short Treat on the Formation of Tumours*, London, 1830) first described certain microscopic crystals in old extravasations of blood; e.g. in apoplectic clots; to these Virchow (*Virch. Archiv.* 1, 383) gave the name hæmatoidin, and recognised that they were derived from the colouring matter of the blood. The same substance occurs sometimes in an amorphous condition. The crystals have also been found in the urine (v. Recklinghausen, Landois). The crystals are identical in form with those of bilirubin, the chief colouring matter of human bile, and give Gmelin's colour reaction with fuming nitric acid. It has the same formula  $C_{44}H_{36}N_4O_{10}$ . Neither hæmatoidin nor bilirubin show spectroscopic bands, but absorb the violet end of the spectrum powerfully. Although Holm (*J. pr.* 100; 142) and Preyer (*Die Blutkristalle*, 187) deny the identity of the two substances, Salkowski (*Med. Chem. Unters.* 3, 436) and the majority of physiological chemists are, however, now of the opinion that the two are identical. Holm and Preyer probably mistook the lipochrome (lutein) of the cow's ovary for hæmatoidin (Thudichum, *Proc. R. S.* 17, 255).

**Other animal pigments.** Bilirubin and the other colouring matters of the bile, stercobilin, the pigment of the faeces, certain urinary pigments, melanin, the black pigment of the skin, retina, and of melanotic sarcomata, are all probably derived from hæmoglobin. The allied pigments myo-hæmatin and the histo-hæmatins will be described under *MUSCULA*. W. D. H.

**HALOGEN ELEMENTS.** The four elements F, Cl, Br, and I are classed together under the name *halogens*, or salt-formers. The name was given by Berzelius (*Vehrbuch*, 1, 266 [5th ed. to those non-oxygenated radicles, simple or compound, which combine with metals to form salts; Berzelius regarded all salts as formed by the union of a positive and a negative radicle. He applied the name *salt-former* to the negative radicles, more especially to those which do not contain oxygen, and yet more particularly to the simple radicles F, Cl, Br, I, and the compound radicle cyanogen. The nomenclature has been maintained as regards the elements F, Cl, Br, and I. The binary compounds of these elements are usually called *haloid salts*. This name was also introduced by Berzelius; he used it to distinguish salts formed by the union of metal with F, Cl, Br, I, or CN from salts formed by the union of two radicles, each of which contained a common element, e.g. oxygen-salts, sulphur salts, selenium-salts, &c.

The halogens are found in combination very widely distributed. Metallic chlorides are very numerous; bromides, iodides, and fluorides occur in smaller quantities. The elements themselves are scarcely found in the free state in nature; iodine is said to exist in minute quantities in sea water. Fluorides of all elements are known except Br, C, Cl, N, O, and some ten or twelve metals (mostly rare metals which have not been thoroughly examined); chlorides of all elements except F have been isolated; bromides of almost all elements except F and O are known; and iodides of all, or almost all, elements except F have been obtained.

The compounds of the halogen elements show resemblances both in composition and properties. If  $X = F, Cl, Br, \text{ or } I$ , the chief metallic halogen compounds may be grouped under the forms:—

- (1)  $MX$ ;  $M = \text{alkali metal, Ag, Cu, or Au}$ ; also Hg and Pt.
- (2)  $MX_2$ ;  $M = Be, Mg, Ca, Zn, Sr, Cd, Ba, Hg$ ; also Cu; In; Sn; Pb; Fe; Ni; Co; the Pt metals.
- (3)  $MX_3$ ;  $M = Al, Ga, In, Tl$ ; As, Sb, Bi; Fe, Cr.
- (4)  $MX_4$ ;  $M = Ti, Ge, Zr, Sn, Ce, Pb, Th, Mo, U$ ; the Pt metals.
- (5)  $MX_5$ ;  $M = Nb, Sb, Bi, Ta$ ; Mo, W.
- (6)  $MX_6$ ;  $M = W$ .

The non-metallic halogen-compounds for the most part belong to the following forms:—

- (i.)  $MX$ ;  $M = H$ .
- (ii.)  $MX_2$ ;  $M = S, O, Se, Te$ .
- (iii.)  $MX_3$ ;  $M = B, N, P, As$ .
- (iv.)  $MX_4$ ;  $M = C, Si, Te$ .
- (v.)  $MX_5$ ,  $M = P$ .

The resemblances in the composition of the halogen-compounds are further brought out by the formulæ of oxyacids. These oxyacids for the most part belong to the four classes  $HXO$ ,  $HXO_2$ ,  $HXO_3$ ,  $HXO_4$ ; but no oxyacid of F has yet been isolated.

The halogens are all strongly electronegative; none of them replaces the hydrogen of acids to form salts. They combine directly with very many elements, and much heat is usually produced in the process. F is especially energetic in its reactions: it reacts with cold water to form

monised O and HF, whereas Cl only reacts rapidly with water at a red heat, and the reactions of Br and I with water at high temperatures are very slow.

A comparison of the binary compounds of the halogens with H, and of the ternary compounds with H and O, brings out the resemblances and differences between the four elements. The compounds HX are all gases at ordinary temperatures; the formula HX expresses the composition of the molecules of each, but at low temperatures the V.D. of hydrogen fluoride is greater than that calculated from the formula HF. According to Thorpe and Hambley (*C. S. Trans.* 1888, 765; 1889, 163) there is no proof of the separate existence throughout any considerable temperature-interval of molecules heavier than those whose composition is expressed by the formula HF. Aqueous solutions of HX all contain acids; whether the acidic reactions of these solutions are the reactions of HX, or of a compound or compounds,  $HX.nH_2O$ , ( $?H_nX.OH$ ), cannot be regarded as yet finally determined (*v. vol. i. p. 534; ii. p. 8*). The readiness with which stable acid fluorides, e.g.  $KF.HF$ ,  $BiF_3.3HF$ , are formed, whereas corresponding chlorides, bromides, and iodides are few in number and unstable, points to the probable existence of  $H_2F_2$ , as the chemically reacting unit of hydrofluoric acid. The formation of these stable acid fluorides, and also of such definite acids as  $SiF_2.2HF$  ( $=H_2SiF_6$ ),  $BF_3.HF$  ( $=HBF_4$ ),  $SnF_4.2HF$  ( $=H_2SnF_6$ ), differentiates F from Cl, Br, and I. But it is to be noted that HCl, HBr, and HI combine with chlorides, bromides, and iodides of Hg, Au, and Pt, to form compounds which react as definite acids, e.g.  $H_2HgCl_2$ ,  $H_2HgI_2$ ,  $HLiPtBr$ ,  $HAuBr$ . The heat of neutralisation of HFAq is 13 to 19 p.c. greater than that of the other acids, HXAq; on the other hand, the relative affinity of HFAq is very small, while HClAq, HBrAq, and HIAq are very strong acids (*cf. AFFINITY*, vol. i. p. 75).

According to the electrolytic dissociation-hypothesis of chemical change in solution (*v. PHYSICAL METHODS*), the small affinity of HFAq indicates that in solution only a few molecules HF (or  $?H_2F_2$ ) are dissociated into their ions; whereas most of the molecules HCl, HBr, and HI are dissociated in aqueous solutions of these compounds. If this is so, it is probable that the affinity of F for H is much greater than that of either Cl, Br, or I for H. The stability of the fluorides generally, and especially the stability of some non-metallic fluorides containing relatively much F, compared with the relatively unstable character of corresponding chlorides, bromides, and iodides, points to the affinity of F for metals and non-metals generally, as being greater than that of any of the other three halogen elements; e.g. compare  $PF_5$  with  $PCl_5$ , or  $BiF_3$  with  $BiCl_3$ .

Br decomposes most iodides with liberation of I; Cl decomposes both bromides and iodides with liberation of Br or I respectively; the reactions of F with chlorides, bromides, and iodides have not been yet examined.

The atoms of the halogens are monovalent in gaseous molecules. The gaseous molecules of Cl, Br, and I are diatomic; but the vapour-densities of bromine and iodine indicate the

gradual dissociation of the diatomic molecules  $Br_2$  and  $I_2$  into the monatomic molecules Br and I as temperature increases. In the case of iodine dissociation is almost complete at about  $1500^\circ$ , but the lowest S.G. obtained for bromine (at c.  $1570^\circ$ ) agrees approximately with that calculated for  $\frac{1}{2}Br_2$ . The results obtained with chlorine at c.  $1500^\circ$  indicate only a very slight dissociation of the diatomic molecule  $Cl_2$ . Experiments in this direction have not yet been made with fluorine. (For details *v. BROMINE*, vol. i. p. 536; *CHLORINE*, vol. ii. p. 11; and *IODINE*.) I dissolves in ether and some other solvents to form red solutions, and in  $CS_2$ , &c., to form violet solutions; Loeb's results (*C. S. Trans.* 1888, 806) indicate that the molecule of I in the red solutions is probably  $I_2$ , and that in the violet solutions the molecule is less complex than this; the values obtained were between  $I_2$  and  $I_3$ .

The halogens show a gradation of prominent physical properties: F is a colourless gas, Cl is a yellowish-green gas easily condensed to a liquid, Br is a dark-red liquid with low B.P., and I is a lustrous greyish-violet solid.

None of the halogens combines directly with O. In their compounds with O and with O and H the halogens show considerable differences. No oxide of F or Br has yet been isolated; the oxides of Cl which certainly exist are  $Cl_2O$  and  $ClO_2$ ; only one oxide of I, viz.  $I_2O_5$ , has been certainly isolated. The oxides of Cl are very unstable explosive gases;  $I_2O_5$  is a stable well-defined solid.  $Cl_2O$  is the anhydride of hypochlorous acid  $HClO$ ;  $ClO_2$  reacts with water to form both chlorous and chloric acids  $HClO_2$  and  $HClO_3$ ;  $I_2O_5$  is the anhydride of iodic acid  $HIO_3$ .

The oxyacids of Cl are  $HClO$ ,  $HClO_2$ ,  $HClO_3$ , and  $HClO_4$ ; only the last has been obtained apart from water, the others are known in aqueous solutions only. The oxyacids of Br are  $HBrO$  and  $HBrO_3$ ; neither is known otherwise than in aqueous solution. The oxyacids of I are  $HIO$ , and  $HIO_3$ ; both have been isolated as solids. No oxyacid of F has yet been obtained. Solutions of the two acids  $HClO$  and  $HBrO$  are obtained by similar processes, viz. by reactions between HgO and ClAq or BrAq; when  $Ba(ClO_3)_2$ ,  $Ba(BrO_3)_2$ , or  $Ba(IO_3)_2$  is decomposed by the proper quantity of dilute  $H_2SO_4$  Aq, a solution of the corresponding acid,  $HClO_3$ ,  $HBrO_3$ , or  $HIO_3$ , is obtained. Salts of these acids are also obtained by oxidising chlorides, bromides, or iodides; the conditions differ somewhat in each case (*v. vol. i. p. 537; ii. p. 15; and IODINE, OXYACIDS OF*, in vol. iii.). The following thermal data regarding the formation of hydric acids and oxyacids of the halogens are taken from Thomsen:—

	M=Cl	M=Br	M=I
[H,M]	22,000	8,340	-6,040
[H,M,Aq]	39,315	28,380	13,170
[H,M,O,Aq]	29,930	26,080	—
[H,M,O,Aq]	23,940	12,420	55,800

Thomsen also gives these data:—

[M,O,Aq]	-8,490	-16,200	—
[HMAq,O]	-15,880	-15,960	42,630

These numbers connect the differences between the relative stabilities of the acids of Cl, Br, and I, with differences between the quantities of energy degraded in their formations from their elements.

From Thomsen's thermal values we might fairly expect  $\text{HIO}_3$  to be a more stable acid than  $\text{HClO}_3$  or  $\text{HBrO}_3$ ; we might also expect  $\text{HIO}_3\text{Aq}$  to be more readily produced by oxidising  $\text{HIAq}$ , than  $\text{HClO}_3\text{Aq}$  or  $\text{HBrO}_3\text{Aq}$  from a solution of the corresponding hydracid; and we might also expect  $\text{HI}$  or  $\text{HIAq}$  to be more unstable than the corresponding compounds of  $\text{Cl}$  or  $\text{Br}$ .

Chlorine water is an oxidising agent; but the oxidising action of bromine water is very small. Thomsen's thermal measurements connect these facts with energy-changes; he gives the following constants of oxidation:—

$$(i) 2[\text{H}, \text{Cl}, \text{Aq}] - [\text{H}_2\text{O}] = 10,270$$

$$(ii) 2[\text{H}, \text{Br}, \text{Aq}] - [\text{H}_2\text{O}] = -11,600.$$

(i) represents the heat produced when chlorine decomposes water with formation of  $\text{HClAq}$  and  $\text{O}$ ; (ii) represents the heat which disappears in the corresponding reaction of  $\text{Br}$  with water.

The heats of formation of  $\text{Cl}_2\text{O}$  and  $\text{I}_2\text{O}_5$  are very different:  $[\text{Cl}_2\text{O}] = -17,980$ ;  $[\text{I}_2\text{O}_5] = 45,030$  (Thomsen). If we compare the heats of formation of the oxyacids of  $\text{Cl}$  and  $\text{Br}$  with the heats of formation of the oxyacids of  $\text{I}$ , we see that the quantity of heat produced in the cases of  $\text{Cl}$  and  $\text{Br}$  decreases as the quantity of  $\text{O}$  increases, but increases in the case of  $\text{I}$  as the quantity of  $\text{O}$  increases (*v. supra*). The heat of formation of periodic acid  $\text{H}_5\text{IO}_6$  is very much greater than that of any other oxyacid of  $\text{I}$ ; Thomsen gives  $[\text{H}_5\text{IO}_6\text{Aq}] = 184,400$ , and  $[\text{HIAq}, \text{O}] = 34,610$ .

Chlorine and iodine are the only halogens which form oxyacids higher than  $\text{HMO}_3$ ; perchloric acid is  $\text{HClO}_4$ , but the only periodic acid which has been isolated is  $\text{H}_5\text{IO}_6$ . The composition of these two acids marks a point of difference between  $\text{Cl}$  and  $\text{I}$ . A great many periodates are known which have few if any analogues among the salts of  $\text{Cl}$  oxyacids. The periodates may be arranged in four classes:

*meta-periodates*, e.g.  $\text{KIO}_4$ , derived from the hypothetical acid  $\text{HIO}_4$  ( $= \text{H}_5\text{IO}_6 - 2\text{H}_2\text{O}$ );

*meso-periodates*, e.g.  $\text{Pb}_2(\text{IO}_4)_2$ , derived from the hypothetical acid  $\text{H}_2\text{IO}_4$  ( $= \text{H}_5\text{IO}_6 - \text{H}_2\text{O}$ );

*para-periodates*, e.g.  $\text{Ba}_3(\text{IO}_4)_3$ , derived from the acid  $\text{H}_3\text{IO}_4$ ;

*di-periodates*, e.g.  $\text{K}_2\text{I}_2\text{O}_7$ , derived from the hypothetical acid  $\text{H}_2\text{I}_2\text{O}_7$  ( $= 2\text{H}_5\text{IO}_6 - 3\text{H}_2\text{O}$ ).

(For details *v. Periodates*, under IODINE, OXYACIDS *OP*.)

The oxyacids of  $\text{Cl}$  and  $\text{Br}$  are all monobasic; but periodic acid  $\text{H}_5\text{IO}_6$  is pentabasic, and iodic acid  $\text{HIO}_3$  or  $\text{H}_2\text{I}_2\text{O}_7$  is probably dibasic (*v. IODINE*, OXYACIDS *OP*).

The affinities of the hydracids of  $\text{Cl}$ ,  $\text{Br}$ , and  $\text{I}$  are approximately equal; the affinity of  $\text{HFAq}$  is very small, less than  $\frac{1}{100}$ th of that of  $\text{HClAq}$ . The affinities of the oxyacids of the halogens, except that of  $\text{HClO}_4\text{Aq}$ , have not yet been determined;  $\text{HClO}_3\text{Aq}$  is nearly as strong an acid as  $\text{HClAq}$ . The data for comparing the increase in the affinity of an acid when  $\text{H}$  is substituted by  $\text{F}$ ,  $\text{Cl}$ ,  $\text{Br}$ , and  $\text{I}$  respectively are as yet very meagre; from the measurements which have been made the substitution of  $\text{Cl}$  seems to raise the affinity a little more than substitution of  $\text{Br}$  or  $\text{F}$ .

In the classification of the elements on the basis of the periodic law (*v. vol. i. p. 351*; also CLASSIFICATION, vol. ii. p. 208) the halogens are placed in Group VII,  $\text{Cl}$ ,  $\text{Br}$ , and  $\text{I}$  in odd series,

(3, 5, and 7), and  $\text{F}$  in an even series (2). Group VII also contains  $\text{Mn}$ . The analogies between  $\text{Mn}$  and the halogens are but feebly marked. Physically  $\text{Mn}$  is a metal; chemically it is both metallic and non-metallic. The permanganates  $\text{Mn}^{+7}\text{MnO}_4$  are generally isomorphous with the perchlorates, and with some of the meta-periodates. There are many gaps in Group VII; at least four elements belonging to even series, and two belonging to odd series have yet to be discovered. The position of  $\text{Mn}$  following a series of metallic elements, and followed by the metals  $\text{Fe}$ ,  $\text{Ni}$ , and  $\text{Co}$ , would lead us to expect pronounced metallic properties in this element. Looking generally at the variations of properties in groups and series, we should expect the analogy between  $\text{Cl}$ , which is the first member of the odd series of Group VII, and  $\text{Mn}$ , which belongs to the even series, to be but feebly marked; we should also expect to find the resemblances between the other even-series members of the group (when they are discovered) to be less distinctly marked than is the case in the lower groups, and we should expect to find all the odd-series members ( $\text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$ , and two elements yet to be discovered) to resemble one another fairly closely.

For details about the individual halogens *v. BROMINE*, *CHLORINE*, *FLUORINE*, and *IODINE*.

M. M. P. M.

**HALOGENS, BINARY COMPOUNDS OF THE.** The four halogen elements form numerous binary compounds both with metals and non-metals. The compositions of the chief compounds in question are represented by general formulæ in the preceding article. Metallic fluorides, chlorides, bromides, and iodides may generally be prepared by dissolving metals or their oxides or carbonates in solutions of  $\text{HF}$ ,  $\text{HCl}$ ,  $\text{HBr}$ , or  $\text{HI}$ , and evaporating; many are also formed by the direct union of the elements; some are produced by reactions between metallic oxides or hydroxides and  $\text{Cl}$ ,  $\text{Br}$ , or  $\text{I}$  (probably a similar reaction will be found to occur with  $\text{F}$ ). Metallic fluorides are not decomposed by heat alone; many of them are unchanged even when heated with carbon or oxygen; a few metallic chlorides are decomposed by heat alone to metal and  $\text{Cl}$ , e.g.  $\text{PdCl}_2$ ; some are reduced by heat to lower chlorides, e.g.  $\text{CuCl}_2$  to  $\text{CuCl}$ ; but the majority are volatilisable without decomposition; metallic bromides and iodides as a class resemble chlorides in their behaviour towards heat; many chlorides, bromides, and iodides are decomposed with formation of oxy-haloid compounds or of oxides by strongly heating in moist air or oxygen. As a class, metallic chlorides, bromides, and iodides are soluble in water; some are decomposed to oxy-haloid salts; on the whole the iodides are less readily decomposed by water than the chlorides or bromides; metallic fluorides are generally insoluble in water; they are distinctly more stable towards water than the other haloid salts. Metallic fluorides very readily combine with  $\text{HF}$  to form acid salts, which are generally decomposed by heat with formation of the normal salt and  $\text{HF}$ . A few chlorides, bromides, and iodides combine with  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$  respectively; but such acid chlorides are comparatively few in number, and are much less stable than the acid bromides.

The non-metallic halogen binary compounds as a class are gasifiable; some, however, are decomposed by heat, e.g. chlorides and bromides of S; generally speaking the fluorides are more stable than the corresponding compounds of the other halogens. Most non-metallic chlorides and bromides are decomposed by water with formation of haloid acid and an oxyacid of the non-metal; in this respect iodides are more stable than chlorides and bromides, and fluorides are more stable than iodides.

Chlorine forms binary compounds with all non-metals except F; bromine with all except F, O, and perhaps N; iodine with all except B; and fluorine with all except Br, Cl, C, O, and N. The binary compounds of the halogens with H are acids, HCl, HBr, and HI are strong acids, but HF has a very small affinity. The binary compounds which the halogens form by combining one with another are not numerous; the chief are  $IF_3$ ,  $ICl$ ,  $ICl_3$ ,  $IBr$ ,  $BrCl$ ; the only one of these which has been gasified without decomposition is  $ICl$ . M. M. P. M.

**HALOID SALTS.** Binary compounds of the halogens F, Cl, Br, I, with metals.

**HAMATHIONIC ACID**  $C_{12}H_{11}SO_{16}$ . An acid produced by the action of  $H_2SO_4$  on euxanthic acid (Erdmann, A. 60, 240). Syrup; decomposed by boiling water.— $Pb_2C_{12}H_{11}SO_{16}$ .

**HARMALINE**  $C_{17}H_{15}N_2O$ . *Harmine dihydride*. [c. 238°]. Occurs, together with harmine, in the seeds of *Perganum harmala*, a plant growing in Southern Russia. These alkaloids make up 4 p.c. of the seeds, and are found in the seed coating, not in the kernel (Göbel, A. 38, 363; Fritzsche, A. 64, 360; 68, 351, 355; 72, 306; 88, 327). Occur probably in the form of phosphates.

**Preparation.**—The seeds are extracted with dilute HOAc or  $H_2SO_4$ , and the brown extract mixed with NaCl. The hydrochlorides of the bases are ppd. together with colouring matter; the pp. is washed with brine, and then treated with pure water, which dissolves the hydrochlorides of the bases. The solution is treated with animal charcoal and the filtrate heated to 60° and mixed with ammonia. Harmine comes down first in minute needles, on further addition of ammonia harmaline is ppd. in minute scales.

**Properties.**—Trimetric octahedra (from alcohol);  $a:b:c = 1:1.804:1.415$ . Sl. sol. water and ether, m. sol. cold alcohol, v. sol. boiling alcohol. On oxidation with  $HNO_3$  it forms harmine. Harmine is also formed when the acid chromate of harmaline is heated to 130°. By heating with HCl it is converted into harmalol.

**Salts.**—The salts of harmaline are yellow and exhibit strong fluorescence.— $B'HCl$  2aq: long yellow prismatic needles; m. sol. water and alcohol.— $B'H_2PtCl_6$ : yellow pp.— $B'H_2CrO_4$ : crystalline.—Acetate is crystalline.— $B'HCy$ : from harmaline hydrochloride and KCy. Formed also by dissolving harmaline in boiling dilute HCl. Thin tables (from alcohol). By heating to 180° or by boiling with water or alcohol it is resolved into harmaline and HCl. It combines with acids; thus HCl forms  $B'HCyHCl$ , a crystalline powder composed of small octahedra.

**Methylo-iodide**  $B'MeI$ . [260°] (O. Fischer & Täuber, B. 18, 400).

**Nitro-harmaline**  $C_{17}H_{13}(NO_2)_2N_2O$ . [120°]. *Chrysoharmine*. Formed by suspending harmaline (1 gr.) in alcohol (7 pts. of 80 p.c.) adding conc.  $H_2SO_4$  (2 pts.) and, when the solution is complete, moderately concentrated nitric acid (2 pts.); the mixture is heated to 100°, and when the reaction is over it is cooled quickly. The liquid then deposits the sulphate of nitro-harmaline, which is washed with alcohol containing  $H_2SO_4$ , dissolved in water, and treated with KOH. It may be further purified by sulphurous acid with which, unlike harmaline and harmine, it forms a sparingly soluble salt. Orange powder, composed of minute prisms (by ppn.); larger crystals are deposited from the alcoholic solution. Sl. sol. cold water, to which, however, it imparts a yellow colour; m. sol. boiling water; sl. sol. cold ether. More soluble in alcohol than harmine or harmaline. It expels  $NH_3$  when heated with ammonium salts.

**Salts.**— $B'HCl$ : small yellow prisms.— $B'H_2PtCl_6$ : yellow pp., which ultimately assumes the form of minute prisms.—**Nitrate**: yellow needles; sl. sol. dilute  $HNO_3$ .— $C_{17}H_{13}Ag(NO_3)_2N_2O$  aq: yellowish-red flocculent pp. obtained by adding ammoniacal silver nitrate to a solution of nitro-harmaline nitrate.—**Normal sulphate**: crystalline pp.— $B'H_2SO_4$ : pale-yellow crystalline powder, nearly insol. cold water.— $B'HCy$ : obtained by dissolving nitro-harmaline in hot alcoholic HCl. Slender yellow needles. Resolved by boiling water into HCl and nitro-harmaline.

**Harmine**  $C_{17}H_{15}N_2O$ . [257°]. Occurs in the seeds of *Perganum harmala* (v. supra). Formed also by the oxidation of harmaline by a mixture of equal parts of alcohol and  $HClAq$  to which a little nitric acid has been added; the liquid is boiled, and on cooling harmine hydrochloride crystallises out in slender needles. The solution of this salt decomposed by  $NH_3$  yields the base.

**Properties.**—Long colourless monoclinic prisms (from alcohol); nearly insol. water, less soluble in alcohol than harmaline, v. sl. sol. ether. Expels ammonia from boiling solutions of its salts. By heating with fuming  $HClAq$  at 140°, harmol and  $MeCl$  are formed (Fischer & Täuber, B. 18, 400).  $CrO_3$  oxidises it to harminic acid.

**Salts.**—Colourless; but in solution they exhibit indigo-blue fluorescence.— $B'HCl$  2aq: needles, sol. water and alcohol, v. sl. sol.  $HClAq$ .— $B'HCy$  (from alcohol).— $B'H_2PtCl_6$ : flocculent pp., becoming crystalline when the liquid is heated.— $B'H_2SO_4$  2aq: concentrically grouped needles.— $B'H_2SO_4$  (from alcohol).— $B'H_2CrO_4$ .— $B'H_2C_2O_4$  aq: radiating needles.

**Methylo-iodide**  $B'MeI$ . [c. 298°]. Long white needles (F. a. T.).

**Di-chloro-harmine**  $C_{17}H_{13}Cl_2N_2O$ . Formed by heating a solution of harmine hydrochloride (2 pts.) in water (100 pts.) to boiling and adding conc.  $HClAq$  (15 pts.), followed by  $KClO_3$  in small quantities until the brownish-red colour which at first appears is changed to pure yellow; on cooling, di-chloro-harmine hydrochloride separates and is washed with dilute  $HClAq$ . The salt is recrystallised from alcohol, and decomposed by boiling  $NaOHAq$ . Needles (from alcohol); insol. cold, v. sl. sol. boiling water, sl. alcohol, ether, benzene, and CS. With

iodine it forms a compound containing 46.5 p.c. iodine ( $C_{12}H_{11}Cl_2N_2O_2$  requires 47.5 p.c.).

**Salts.**—The salts of di-chloro-harmine are v. sl. sol. dilute acids; the normal salts are partially decomposed by much water, di-chloro-harmine separating. Ammonia ppts. the base from its salts as a jelly; NaOHAq also forms a gelatinous pp. which, however, becomes crystalline on long boiling with a large excess of NaOHAq.—B'HCl2aq: needles (from water); separated from its aqueous solution by NaCl as a jelly which subsequently becomes crystalline. B'HNO<sub>3</sub>: ppd. as a jelly, changing to needles, by adding HNO<sub>3</sub> to a solution of di-chloro-harmine in dilute HNO<sub>3</sub>.

**Nitro-harmine**  $C_{12}H_{11}(NO_2)N_2O$  (Fritzsche, A. 88, 328; 92, 330). Produced by the action of nitric acid on harmaline or nitro-harmaline. Prepared by dissolving harmaline (1 pt.) in water (2 pts.) and the requisite quantity of HOAc, and then adding HNO<sub>3</sub> (12 pts. of S.G. 1.40) in a thin stream. The liquid is boiled as long as nitrous fumes escape, and the nitro-harmine then ppd. by KOH. Yellow octahedra which soon change to needles (from alcohol); sl. sol. cold, m. sol. boiling, water. sl. sol. ether.—Hydrochloride: B'HCl2aq: slender yellow needles.—Di-iodide B'I<sub>2</sub>. Separates as minute yellowish-brown needles on mixing the boiling solutions of iodine and nitro-harmine in alcohol. In water, alcohol, and ether it is nearly insol. in the cold, but sl. sol. on warming. Boiling alcohol resolves it into iodine and nitro-harmine; boiling dilute H<sub>2</sub>SO<sub>4</sub> acts in like manner.

**Bromo-nitro-harmine**  $C_{12}H_{11}Br(NO_2)N_2O$ . Ppd. by addition of bromine, followed by ammonia, to a dilute solution of a salt of nitro-harmine. When bromine-water is added to its solution in hot dilute alcohol there is deposited on cooling minute yellow needles of the dibromide  $C_{12}H_{11}Br_2(NO_2)N_2O$ .

**Chloro-nitro-harmine**  $C_{12}H_{11}Cl(NO_2)N_2O$ . Produced by the action of chlorine on nitro-harmine or of aqua regia on harmaline.

**Preparation.**—Harmaline (1 pt.) is dissolved in water (2 pts.), and the requisite quantity of HOAc, and the solution is poured into boiling nitric acid (12 pts. of S.G. 1.40) mixed with fuming HClAq (2 pts.). When the reaction is over a solution of NH<sub>4</sub>Cl mixed with lumps of ice is poured into the liquid, which is afterwards further diluted, and ppd. by NaOHAq. Bright yellow brittle masses composed of minute needles. Ppd. from its salts by NH<sub>3</sub> as a jelly. Sl. sol. cold, m. sol. boiling water and boiling alcohol. Sl. sol. ether. Iodine solution forms slender needles of  $C_{12}H_{11}I_2(NO_2)N_2O$ , sol. alcohol.

**Salts.**—B'HCl: slender, hair-like needles, m. sol. water. Ppd. from its aqueous solution by HClAq. as a jelly, and by NaCl as white flocculi.—B'H<sub>2</sub>PtCl<sub>6</sub>: slender yellow prisms (from alcohol).

**Harmine tetrabromide**  $C_{12}H_{11}N_2OBr_4$ . Obtained as a reddish-yellow flocculent pp. on adding excess of bromine to a cold solution of harmine in dilute H<sub>2</sub>SO<sub>4</sub> (O. Fischer, B. 22, 638). Reconverted into harmine by SO<sub>2</sub> or by warm aqueous Na<sub>2</sub>CO<sub>3</sub>.

**Harmine tetrahydride**  $C_{12}H_{17}N_2O$ .

**Harmaline dihydride**. [199°]. Obtained by reducing a hot concentrated solution of harmaline

in alcohol by means of sodium (O. Fischer, B. 22, 638). Formed in the same way from harmine. Irregular pointed needles (from alcohol). Its solutions fluoresce pale bluish-green, becoming deep-green on addition of FeCl<sub>3</sub> or AgNO<sub>3</sub>. Gives a nitrosamine  $C_{12}H_{15}N_2O$ .

**Apo-harmine**  $C_{12}H_{13}N_2$ . [183°]. Got by distilling harmine acid (v. *infra*) in a partial vacuum in portions of .5 g. at a time (O. Fischer, B. 22, 640).—B'HAuCl<sub>4</sub>: yellow needles.—B'HIaq: fan-shaped groups of white needles (from MeOH), decomposing at 220° without melting.

**Apo-harmine tetrabromide**  $C_{12}H_{13}N_2Br_4$ . A lemon-yellow pp. got by adding excess of bromine water to a solution of apo-harmine in dilute H<sub>2</sub>SO<sub>4</sub>.

**Apo-harmine dihydride**  $C_{12}H_{15}N_2$ . [49°]. (262°). Obtained by reducing apo-harmine with conc. HIAq and red phosphorus at 160°. Tables (from ether-ligroin). Smells of excrement of mice. From ether it separates with ether of crystallisation. Its solution in dilute H<sub>2</sub>SO<sub>4</sub> exhibits violet fluorescence. Its hydrochloride colours pine-wood deep-orange.—B'HCl: felted needles.—B'H<sub>2</sub>PtCl<sub>6</sub>2aq: orange crystals.—B'HAuCl<sub>4</sub> [149°]: reddish-brown needles.

**Nitro-amine**  $C_{12}H_{13}(NO)N_2$ . [135°]. Small needles (from hot water). May be sublimed.

**Harmol**  $C_{12}H_{13}N_2O$ . [321°]. Formed by elimination of a methyl group from harmine  $C_{13}H_{17}N_2O$ , by heating it with fuming HCl at 140° (O. Fischer a. Täuber, B. 18, 402). Small needles. V. e. sol. aqueous alcohol, sl. sol. absolute alcohol, nearly insol. water. Dissolves in acids and in caustic alkalis. The acid solutions have a violet fluorescence.

**Harmine acid**  $C_{13}H_{17}N_2O_2$ . [345°]. Formed by oxidation of harmine in HOAc with CrO<sub>3</sub> (O. Fischer a. Täuber, B. 18, 403). Formed in like manner from harmaline. Silky needles, sl. sol. hot water, nearly insol. alcohol, ether, chloroform, and benzene. On heating to its melting-point it evolves CO<sub>2</sub>, and yields apo-harmine  $C_{12}H_{13}N_2$  which melts at [183°].

**Harmalol**  $C_{12}H_{17}N_2O$ . Obtained as hydrochloride by heating harmaline (3 g.) with conc. HClAq (10 c.c.) at 150°. The base may be liberated by NaOH. Red needles, sol. hot water, sl. sol. benzene, sol. chloroform and acetone. Readily oxidised by air. It crystallises from dilute alcohol with 3aq.—B'HCl2aq: crystals.—B'H<sub>2</sub>PtCl<sub>6</sub>.

**Acetyl derivative**  $C_{12}H_{15}AcN_2O$ . Nodules.

**Harmolic acid**  $C_{12}H_{13}N_2O_2$ . [247°]. Formed by fusing harmol with KOH, and ppg. the aqueous solution of the melt with H<sub>2</sub>SO<sub>4</sub>. Small needles (from hot water). The solution of its ammonium salt gives amorphous pps., with salts of Pb, Cu, Ca, and Ag. On distilling in a partial vacuum harmolic acid yields a sublimate  $C_{12}H_{13}N_2O$  in small needles, sl. sol. ether, m. sol. alcohol, forming a solution that fluoresces violet. This body appears to be a phenol and a base. It forms a platinum-chloride B'H<sub>2</sub>PtCl<sub>6</sub> crystallising from hot water in small prisms united in stars, sl. sol. cold water, decomposing at about 180° (O. Fischer, B. 22, 642).

**HARTIN**  $C_{12}H_{15}O$ . *Psatyryn*. [210°]. (260°). A fossil resin resembling hartite. Crystallises from petroleum in triclinic needles. Sl.

sol. ether and boiling alcohol (Schrötter, P. 54, 145).

**HARTITE** ( $C_8H_{10}$ )<sub>2</sub>. [74°]. S.G. 1.05. A fossil resin found in Styria (Saidinger, P. 54, 261; Rumpf, J. pr. 107, 189). White triclinic crystals. V. sol. ether, m. sol. alcohol.

**HATCHETIN**. C. 86 p.c., H. 14 p.c. [46°]. S.G. 1.53-916. A transparent fossil resin found in the coal measures of Glamorganshire (Johnston, P. M. 12, 338). Sl. sol. boiling alcohol, m. sol. hot ether.

**HEAT** v. PHYSICAL METHODS, section Thermal.

**HECDECANE** v. HEXADECANE.

**HEDERIC ACID**  $C_{18}H_{34}O_8$ . A substance occurring in the berries and leaves of the ivy (*Hedera helix*) (Posselt, A. 89, 62; Hartsen, Ar. Ph. April 1875; Davies, Ph. [3] 7, 275; 8, 205). Needles or delicate scales (Posselt). Davies found it to be uncrystallisable. V. sol. hot alcohol, v. sl. sol. ether,  $CS_2$ , chloroform, benzene, and water. Its solution does not redden litmus. Conc.  $H_2SO_4$  colours it a splendid violet, the colour lasting some days; on pouring into water a flocculent greenish pp. is formed. According to Davies 'hederic acid' is not an acid.  $HNO_3$  forms a nitro-derivative  $C_{18}H_{32}(NO_2)_2O_8$ , v. sol. chloroform. Block (Ar. Ph. [3] 26, 953) finds in ivy-leaves a glucoside  $C_{18}H_{34}O_8$  2aq.

**HELENIN**  $C_8H_{10}O$ . [110°]. Occurs in the root of elecampane (*Inula helenium*), from which it may be extracted with hot alcohol (Gerhardt, A. 34, 192; 52, 389; Gerh. A. 296; Kaller, B. C, 1506). Needles, nearly insol. water, v. sol. alcohol. The crystals first obtained from the alcohol melt at 72°, being a mixture of helenin and inula-camphor (64°); the latter is got rid of by repeated crystallisation from alcohol.

**HELIANTHIC ACID**  $C_{18}H_{34}O_8$ . An acid occurring in sunflower seeds (Ludwig a. Kromayer, Ar. Ph. [2] 99, 1, 285). Boiling dilute HCl splits it up into a fermentable sugar and an acid violet colouring matter.

**HELIANTHIN** v. Di-methyl-amido-benzene-azo-benzene-sulphonic acid.

**HELICHRYSIN**. A yellow pigment contained in the involucre bracts of *Helichrysum bracteatum* (Rosoll, M. 5, 94). Amorphous yellow mass, sl. sol. cold, v. sol. boiling, water, alcohol, and ether.

**HELICIN**  $C_{18}H_{34}O$ , i.e.  $(C_8H_{10}O)_2C_2H_4CHO$ . Glucoside of o-oxy-benzoic aldehyde. Mol. w. 284. [170°] (S.); [174°] (P.); [175°] (M).  $[\alpha]_D^{20} = -60.43$  in a 1.4 p.c. aqueous solution at 20° (Wegscheider, B. 18, 1600). S. 1.6 at 8°.

**Formation**.—1. By the action of very dilute  $HNO_3$  upon salicin ( $C_6H_7O_5O$ )  $C_6H_7CH_2OH$  (Piria, A. Ch. [3] 14, 287; B. 14, 804; Sorokin, J. pr. [2] 37, 332).—2. By boiling its benzoyl derivative with magnesia (Piria, A. 96, 380).—3. By the action of aceto-chlorhydrone  $C_2H_5ClAcO_2$  on potassium salicylic aldehyde, the substances being mixed in alcoholic solution and left for several days (Michael, Am. 1, 808; C. R. 89, 355).

**Preparation**.—Pulverised salicin (1 pt.) is mixed with nitric acid (10 pts. of S.G. 1.157) and the mixture left to itself; after 24 hours the salicin is dissolved and crystals of helicin have separated. They are washed with ether.

**Properties**.—Very slender, white silky needles (containing 2aq). Neutral, slightly bitter, sl. sol. cold, v. sol. boiling, water, sol. alcohol, insol. ether. At 100° it gives off its water of crystallisation. Its solutions are levorotatory.  $FeCl_3$  gives no colouration. Conc.  $H_2SO_4$  dissolves it with yellow colour. With  $NaHSO_4$  helicin forms a hygroscopic crystalline mass of  $C_{18}H_{34}O_2NaHSO_4$  (Schiff, A. 210, 128).

**Reactions**.—1. Under the influence of emulsin or of boiling dilute acids or alkalis, helicin is resolved into glucose and o-oxy-benzoic (salicylic) aldehyde.—2. Sodium-amalgam reduces helicin to salicin (Lesensko, Z. 1864, 577; cf. Swarts, Institut, 1865, 325).—3. When hot alcoholic solutions of helicin and urea are mixed together, and the liquid is allowed to evaporate, there is formed a thick syrup which, when kept over  $H_2SO_4$ , slowly solidifies. The product is the di-ureide  $C_{18}H_{34}O_2O.C_2H_4.CH(NH.CO.NH_2)_2$ , and forms a hygroscopic crystalline powder, v. sol. water, forming a solution that is ppd. by  $Hg(NO_3)_2$ , but not by  $HNO_3$  (H. Schiff, G. 12, 460). 4. An alcoholic solution of thio-urea forms  $C_{18}H_{34}O_2O.C_2H_4.CH(NH.CS.NH_2)_2$ , a very hygroscopic crystalline powder (Schiff).—5. Aniline forms the anilide  $C_{18}H_{34}O_2O.C_2H_4.CH.NPh$ , a yellow powder (containing aq), sol. alcohol and ether, insol. water. It is prepared by gently heating helicin with aniline, treating the product several times with acetic acid to remove excess of aniline, dissolving the residue in alcohol, adding ether, filtering, and ppg. with water (H. Schiff, Z. [2] 4, 638; A. 154, 31). By heating with aniline at 120° it is converted into the dianilide  $C_{18}H_{32}N_2O_2$ . Both anilides are resolved by boiling dilute  $H_2SO_4$  into glucose, helicin, and aniline.—6. Toluylene-m-diamine forms in like manner  $(C_{18}H_{34}O_2O.C_2H_4.CH.N)_2C_2H_4Me$ , which crystallises in orange-red tufts; its solution exhibits marked green fluorescence.—7. By dissolving m-amido-benzoic acid in a cold aqueous solution of helicin a transparent vitreous mass is produced, which crystallises from alcohol in colourless plates [142°]. This compound is  $C_{18}H_{34}O_2O.C_2H_4.CH(OH).NH.C_6H_4.CO_2H$ . On heating with acids it is split up into glucose, m-amido-benzoic acid, and salicylic aldehyde (H. Schiff, G. 10, 470).—8. Amido-cuminic acid forms in like manner the crystalline compound  $C_{18}H_{34}O_2O.C_{10}H_{17}NO_2$ .—9. By the action of glucose and excess of  $HOAc$  on helicin there is formed amorphous  $C_{18}H_{34}O_2O.C_2H_4.CH<O>C_6H_4O$  (H. Schiff, A. 244, 26).—9. By adding leucine to an aqueous solution of helicin saturated with gaseous sulphurous acid there is formed  $C_{18}H_{34}O_2O.C_2H_4.CH(OH)SO_3NH_2.C_6H_4.CO_2H$ , which crystallises with difficulty. Other amido-acids behave in like manner.—10. A solution of helicin (15 pts.) in water (500 pts.) heated to 55° and alternately treated with an aqueous solution of caustic soda (5 p.c. solution) and acetone (5 pts.) dissolved in water (40 pts.) deposits on cooling crystals of the glucoside of o-oxy-di-styryl ketone  $(C_{18}H_{34}O_2O.C_2H_4.CH(OH).CO [257°]$ , while the filtrate on evaporation deposits the glucoside of oxy-di-styryl methyl ketone  $C_{18}H_{34}O_2O.C_2H_4.CH(OH).CO.CH_3$  [192°], of which the oxim melts at 178° (Tiemann a. Kees, B. 18, 1964).

**Tetra-acetyl derivative**  $C_6H_4Ac_4O_2.C_6H_5.CHO$ . Formed by mixing helicin with  $AcCl$ ; after 24 hours the solution is heated to  $60^\circ$ , and the product extracted with ether and crystallised from alcohol (H. Schiff, Z. [2] 5, 1; A. 154, 22). Shining prisms; insol. water, sl. sol. ether and cold alcohol, v. e. sol. hot alcohol. Resolved by boiling dilute  $H_2SO_4$  into glucose,  $HOAc$ , and salicylic aldehyde. With aniline at  $80^\circ$  it forms the anilide  $C_6H_4Ac_4O_2.O.C_6H_5.CH:NPh$ , a yellowish powder, sol. alcohol.

**Benzoyl derivative**  $C_6H_4BzO_2.O.C_6H_5.CHO$ . Obtained by dissolving populin (1 pt.) in nitric acid (11 pts. of S.G. 1.8). Formed also by treating helicin with  $BzCl$ . Tufts of silky needles; sl. sol: boiling water, m. sol. alcohol, insol. ether. Not attacked by emulsin, but boiling dilute acids and alkalis split it up into benzoic acid, glucose, and salicylic aldehyde. Boiling with water and magnesia resolves it into magnesium benzoate and helicin. Sodium-amalgam reduces it to populin  $C_6H_4BzO_2.O.C_6H_5.CH_2OH$ . Aniline at  $150^\circ$  forms a brown resinous di-anilide  $C_{12}H_{14}N_2O_4$ .

**Tetra-benzoyl derivative**  $C_6H_4Bz_4O_2.O.C_6H_5.CHO$ . From helicin and  $BzCl$  at  $160^\circ$ . Amorphous. Sol. alcohol and ether, nearly insol. water. Aniline at  $150^\circ$  forms a brown resinous di-anilide  $C_{12}H_{14}N_2O_4$ .

**Phenyl hydrazide**  $C_6H_4(OC_6H_5O_2).CH:NH.C_6H_5$ : [ $\alpha$ :  $187^\circ$ ]; white slightly crystalline solid. Sol. alcohol, ether, and hot water, nearly insol. cold water. By emulsin it is split up into glucose and salicylic aldehyde pphenyl-hydrazide (Tiemann & Kees, B. 18, 1657).

**Oxim**  $C_6H_4(OC_6H_5O_2).CH:NOH$ : [ $190^\circ$ ]; fine white needles containing aq. Sol. water, more sparingly sol. alcohol, insol. ether. By emulsin it is split up into glucose and salicyl-aldoxim. It is levorotatory (Tiemann & Kees, B. 18, 1662).

**Bromo-helicin**  $C_6H_4BrO_2.aq$ : gelatinous, drying up to an amorphous mass.

(a) **Chloro-helicin**  $C_6H_4ClO_2$ . Obtained by agitating helicin with water in a vessel filled with chlorine. Small needles containing  $\frac{3}{4}$  aq (from water). Sometimes it separates as an amorphous jelly. Nearly insol. cold, m. sol. hot, water; m. sol. alcohol. Emulsin or boiling dilute acids hydrolyse it, forming chloro-salicylic aldehyde and glucose.

(b) **Chloro-helicin**  $C_6H_4ClO_2$ . A white granular substance obtained by passing chlorine into an alcoholic solution of helicin. Insol. water, nearly insol. boiling alcohol, not decomposed by emulsin, acids, or alkalis.

**Isosalicin**  $C_6H_4O_2$ . Formed by heating helicin to  $185^\circ$ . Formed also by moistening helicin with dilute (1 p.c.) nitric acid, leaving it for some days exposed to the air, and then heating to  $110^\circ$  (H. Schiff, B. 14, 818; G. 11, 112). Jelly; drying up to an amorphous powder. Decomposes at  $250^\circ$  without previous fusion. Sl. sol. water, alcohol, cold  $KOH$  aq, and  $HOAc$ . Boiling dilute  $H_2SO_4$  slowly splits it up into glucose and salicylic aldehyde. By warming with very dilute  $HCl$  aq it is changed into ordinary helicin.

**Helicoidine**  $C_{12}H_{14}O_4$ . This substance, which may be regarded as a compound of helicin with salicin, is obtained by treating salicin with very dilute nitric acid (S.G. 1.068) (Piria, A. Ch. [3] 14, 292). Needles containing  $\frac{1}{4}$  aq (from boiling water). Split up by emulsin and by dilute alkalis into glucose, salicylic aldehyde, and saligenin. Aniline at  $70^\circ$  forms the amorphous di-anilide  $C_{12}H_{14}N_2O_4$ .

**Octo-acetyl derivative**  $C_{12}H_{14}Ac_8O_4$ : [ $380^\circ$ ]. From helicoidine and  $Ac_2O$  at  $100^\circ$  (H. Schiff, A. 154, 28). Drusic aggregates; insol. water, v. sol. alcohol and ether.

**HELLEBORIN**  $C_{12}H_{14}O_6$ . A glucoside that occurs sparingly in black hellebore (*Helleborus niger*) and more abundantly in green hellebore (*H. viridis*) (Husemann & Marmé, A. 185, 55; cf. Weppen, Ar. Ph. [3] 2, 101, 193). Prepared by extracting old roots of green hellebore with alcohol, evaporating the extract, boiling the residue with water, and evaporating the aqueous extract till crystals are deposited on cooling. White, concentrically grouped needles (from alcohol), insol. cold water, sl. sol. ether, v. sol. boiling alcohol and chloroform. Decomposes when heated above  $250^\circ$ . Conc.  $H_2SO_4$  colours it deep red, and then dissolves it with the same colour. Helleborin is a stronger narcotic than helleborein. It is resolved by boiling with dilute acids, or more completely with conc.  $ZnCl_2$  aq, into glucose and helleboreisin  $C_{10}H_{12}O_4$ . Helleboreisin is a resinous body, insol. water, sl. sol. ether, v. sol. boiling alcohol; water separates it from its alcoholic solution as a flocculent pp.

**Helleborein**  $C_{12}H_{14}O_{11}$ . Occurs more abundantly in black than in green hellebore, but is present in greater quantity than helleborin even in the latter. The aqueous decoction of the root is ppd. with lead subacetate, the concentrated filtrate freed from excess of lead by sodium sulphate and phosphate, and the filtrate concentrated and ppd. with tannin. The pp. is stirred up with alcohol and  $PbO$ , dried, and exhausted with boiling alcohol; the helleborein is ppd. from the strongly concentrated alcoholic solution by ether. Transparent nodular groups of minute needles (from alcohol); on exposure to air these crumble to a yellowish-white hygroscopic powder. Helleborein has a sweetish taste, is v. e. sol. water, m. sol. alcohol, and insol. ether. It is poisonous. The aqueous solution, which scarcely reddens litmus, dries up to an amorphous mass which loses water at  $120^\circ$ , becomes straw-yellow at  $160^\circ$ , brown at  $220^\circ$ , and carbonises above  $280^\circ$ . Conc.  $H_2SO_4$  dissolves it with brownish-red colour changing to violet. Alkalis and alkaline earths have no action upon it. Boiling dilute acids split it up into glucose and helleboretin. Helleboretin is deposited as a dark violet-blue pp. which, when dry, forms a grey-green amorphous powder, melting above  $200^\circ$ , insol. water and ether, sol. conc.  $H_2SO_4$ , forming a brownish-red solution whence it is ppd. by water in its original state. The alcoholic solution of helleboretin is red, and gives a brown colouration with  $H_2SO_4$  (Greenish, C. J. 88, 719; Ph. [3] 10, 909, 1018). Helleboretin is not poisonous.

**HEMELLITHENE** v. **HEMELLITHENE**.

**HEMELLITHENE-CARBOXYLIC ACID**

**TRI-METHYL-AMMONIUM ACID.**

**HEMELLITHENE SULPHONIC ACID v.**

**TRI-METHYL-BENZENE-SULPHONIC ACID.**

**HEMI-ALBUMEN v. PROTEIDS.**

**HEMI-COLLIN v. PROTEIDS, Appendix C.**

**HEMIMELLITHENE**  $C_6H_5Me$  [1:2:3]. *c*-Tri-methyl-benzene. (175°). Formed by distilling (a)-cuminic acid with lime (O. Jacobsen, *B.* 15, 1857; 19, 2517). Formed also by the action of sodium upon a mixture of (2,1,3)-bromo-xylene and MeI (O. Jacobsen a. Deike, *B.* 20, 903).

Hemimellithene may also be isolated from coal-tar oil. It forms a tri-bromo-derivative  $C_6Br_3Me$ , [209°]. Coal-tar oil also contains another hydrocarbon boiling at 175° which yields a very soluble sulphamide [123°] and gives on oxidation two acids [121°] and [99°] (Jacobsen, *B.* 19, 2511).

**HEMIMELLITHENOL**  $C_6H_5O$  *i.e.*  $C_6H_5Me(OH)$  [5:4:3:1]. [81°]. Formed by fusing the sulphonic acid of Hemimellithene with potash (O. Jacobsen, *B.* 19, 2518). Long flat needles, sol. alcohol and ether. Not coloured by  $FeCl_3$ .

**HEMIMELLITHIDINE v. CUMIDINE.**

**HEMIMELLITHYLIC ACID v. DI-METHYL-BENZOIC ACID.**

**HEMIMELLITIC ACID**  $C_6H_5O_2$  *i.e.*  $C_6H_4(CO_2H)_2$  [1:2:3]. *Hemimellithic acid*. *Benzene c-tri-carboxylic acid*. Mol. w. 210. [185°]. Formed, together with phthalic anhydride, by heating the hydride of mellophanic acid  $C_6H_4(CO_2H)_2$  with  $H_2SO_4$  (Baeyer, *A. Suppl.* 7, 31). Needles; begins to melt at 185°, being decomposed into phthalic anhydride, benzoic acid,  $CO_2$ , and  $H_2O$ . M. sol. cold water. Ppd. from its concentrated aqueous solution by  $HCl$  (difference from phthalic acid).— $Ba_2A''$ , 5aq: short thick needles, v. sol. water.— $Ag_2A''$ : flocculent pp.

**HEMI-PEPTONE v. PROTEIDS.**

**HEMIPIC ACID**  $C_{10}H_{10}O_5$  *i.e.*

$C_6H_5(OMe)_2(CO_2H)_2$  [1:2:3or5:4]. *Di-methyl derivative of di-oxy-phthalic acid*. Mol. w. 226. [180°].

**Formation.**—1. By the oxidation of opianic acid  $C_6H_5(OMe)_2(CHO)(CO_2H)$  by  $PbO_2$  and  $H_2SO_4$  (Wöhler, *A.* 50, 17), by aqueous  $PtCl_4$  (Blyth, *A.* 50, 36, 43), or by chromic acid mixture (Matthiessen, *Pr.* 17, 841).—2. By the oxidation of narcotine by dilute  $HNO_3$  (Anderson, *A.* 86, 194), by  $PbO_2$  and  $H_2SO_4$ , by  $MnO_2$  and  $H_2SO_4$  (Wöhler; Liechti, *A. Suppl.* 7, 150), or by aqueous  $PtCl_4$  (Blyth). In these reactions the narcotine is first converted into opianic acid.—3. Together with meconine  $C_6H_5(OMe)_2<\begin{smallmatrix} OH \\ CO \end{smallmatrix}>O$ , by fusing opianic acid with potash (Matthiessen a. Foster, *Pr.* 11, 58; *C. J.* 15, 346; Beckett a. Wright, *U. S.* 29, 281).—4. By the oxidation of narceine.—5. By the oxidation of berberine (E. Schmidt, *B.* 16, 2589; Perkin, jun., *C. J.* 55, 71).—6. By the oxidation of papaverine by  $KMnO_4$  (Goldschmidt, *M.* 6, 380).—7. By boiling di-azo-hempic acid (from amido-hempic acid) with alcohol (Liebermann, *B.* 19, 2278; Grüns, *B.* 19, 2303).—8. Formed, together with cinchomeronic acid, by the action of 4 p.c. alkaline  $KMnO_4$  on the di-methyl derivative of di-oxy-isquinoline (Goldschmidt, *M.* 9, 827).

**Preparation.**—Opianic acid is converted by hydroxylamine hydrochloride into opianic oxim

anhydride which is then boiled with aqueous  $KOH$ . The product is acidified and the hemipic acid is extracted with ether (Goldschmidt, *M.* 9, 765).

**Properties.**—Monoclinic efflorescent crystals (containing 1aq, aq, 2aq, or 2½aq). After drying at 100°, its melting-point varies from 167° to 175° according to the rapidity with which it is heated (G.). Sl. sol. cold water, m. sol. alcohol and ether. Its aqueous solution is acid in reaction. Sublimes in shining laminae. Gives an orange colouration with  $FeCl_3$ . Gives the fluorescein reaction.

**Reactions.**—1. By boiling with  $HClAq$  or  $HIAq$  it is resolved into  $MeCl$  (or  $MeI$ ) and the methyl derivative of di-oxy-phthalic acid (nor-hempic acid)  $C_6H_4(OH)(OMe)(CO_2H)_2$ , which then splits up into  $CO_2$ , and the methyl derivative of protocatechuic acid (isovanillic acid)  $C_6H_4(OMe)(OH)(CO_2H)$  [251°].—2. By heating with  $HClAq$  at 170° it is resolved into  $MeCl$ , protocatechuic acid and  $CO_2$  (Wegscheider, *M.* 4, 270).—3. Heated with seven times its weight of  $KOH$  and a little water at 210° for fifteen minutes, it is converted into protocatechuic acid.—4. Distillation with *soda-lime* gives the di-methyl derivative of pyrocatechin (Beckett a. Wright).—5. Conc.  $H_2SO_4$  converts it on heating into rufopin (Liebermann a. Chojnacki, *A.* 162, 327).

**Salts.**— $NH_4A$  aq. Needles.— $KHA$  1aq: large hexagonal tables, v. sol. water and alcohol, insol. ether.— $Ag_2A''$ : white pp. insol. water.—Barium salt: when a solution of the barium salt is boiled, shining crystalline plates are deposited; the liquid on cooling redissolves this pp., but after standing for some hours, feathery tufts of very small silky needles separate; these dissolve on heating, and the crystalline plates are again deposited (Matthiessen a. Foster).—Ferric salt: orange-yellow pp.—Lead salt: white pp. insol. water, sol.  $Pb(OAc)_2Aq$  whence it separates as transparent nodules.

(a) *Methyl ether*.

**HEMIPIC ACID**  $C_6H_5(OMe)_2(CO_2H)_2$  [4:3or5:2:1]. [122°]. Formed by oxidising methyl opianate with aqueous  $KMnO_4$  at 90° (Wegscheider, *M.* 3, 859). Long trimetric needles (containing aq or 1½aq). Melts at 98° in its water of crystallisation. Sl. sol. cold, m. sol. hot, water, v. sol. alcohol, ether, and benzene, almost insol. ligroin. Its aqueous solution is feebly acid in reaction, and gives a golden pp. with  $FeCl_3$ . On heating to 200° it gives hemipic anhydride. Distillation with lime gives the di-methyl-derivative of methyl protocatechuate, methyl-di-oxy-phthalic acid, hemipic acid, the methyl derivative of protocatechuic acid (isovanillic acid) and protocatechuic acid. By heating with conc.  $HClAq$  at 120° it is resolved into  $MeCl$ , hemipic acid  $C_6H_5(OMe)(OH)(CO_2H)_2$ , isovanillic acid  $C_6H_5(OMe)(OH)(CO_2H)$  [4:8:1], and protocatechuic acid.

(b) *Methyl ether*.

**HEMIPIC ACID**  $C_6H_5(OMe)_2(CO_2H)_2$  [4:3or5:1:2]. [182°]. Formed by passing  $HCl$  into a solution of hemipic acid in  $MeOH$  (Wegscheider, *M.* 3, 859; cf. Anderson, *A.* 86, 195). Trimetric crystals (from chloroform); a:b:c = 624:1:768. V. sol. water, alcohol, ether, and benzene. Its aqueous solu-

tion gives no pp. with  $\text{FeCl}_3$ . At  $200^\circ$  it yields hemipic anhydride.

**Ethyl ether**  $\text{C}_6\text{H}_5(\text{OMe})_2(\text{CO}_2\text{Et})(\text{CO}_2\text{H})$ . [182°] (A); [142°] (W.). Formed by passing  $\text{HCl}$  into a solution of hemipic acid in alcohol. Needles (from  $\text{MeOH}$ ) or monoclinic prisms (from benzene); v. sl. sol. cold, m. sol. hot, water; v. e. sol.  $\text{MeOH}$ , v. sl. alcohol and ether. Its aqueous solution is pptd. by  $\text{FeCl}_3$ .

**Anhydride**  $\text{C}_{10}\text{H}_8\text{O}_4$ . [167° cor.]. Formed by heating hemipic acid at  $180^\circ$  for an hour, and crystallising from alcohol (Beckett & Wright, *C. J.* 29, 281). Formed also by treating hemipic acid with  $\text{PCl}_5$  (Prinz, *J. pr.* [2] 24, 370). Shining needles. V. e. sol. hot benzene, v. sol. hot alcohol, m. sol. ether, insol. ligroin. Reduced by boiling with zinc-dust and  $\text{HOAc}$  to pseudo-mecconine. Boiling dilute alcoholic potash converts it into mono-ethyl hemipate (Matthiessen & Wright, *Pr.* 17, 341).

**Imide**  $\text{C}_{10}\text{H}_8\text{NO}_4$ , &c.

$\text{C}_6\text{H}_5(\text{OMe})_2\langle\text{CO}\rangle\text{NH}$  (?). [230°]. Formed by distilling ammonium hemipate (Liebermann, *B.* 19, 2278). Formed also by molecular change from the isomeric compound opianic-oxim-anhydride by heating the latter to its melting-point [115°], heating it with conc.  $\text{H}_2\text{SO}_4$ , or with alcohol containing a trace of  $\text{HCl}$ . Hence it is produced in place of the oxim-anhydride by boiling opianic acid with an alcoholic solution of hydroxylamine hydrochloride (Liebermann, *B.* 19, 2923). Long slender colourless needles (from alcohol). The dilute alcoholic and aqueous solutions fluoresce blue. Sublimable. Dissolves in caustic alkalis but not in  $\text{Na}_2\text{CO}_3\text{Aq}$ . Hot  $\text{KOH}$  converts it into hemipic acid and  $\text{NH}_3$ . Boiling with tin and conc.  $\text{HCl}$  converts it into 'hemipimidine'  $\text{C}_{10}\text{H}_8\text{NO}_4$ , or

$\text{C}_6\text{H}_5(\text{OMe})_2\langle\text{CH}_2\text{CO}\rangle\text{NH}$  (?), [181°], which crystallises from benzene-ligroin in laminæ and gives a nitrosamine  $\text{C}_{10}\text{H}_8(\text{NO})\text{NO}$ , [156°], whence hot aqueous  $\text{NaOH}$  forms nitrogen and pseudo-mecconine  $\text{C}_{10}\text{H}_8\text{O}_4$  (Salomon, *B.* 20, 884).— $\text{C}_{10}\text{H}_8\text{KNO}_4$ : crystalline solid.— $\text{C}_{10}\text{H}_8\text{AgNO}_4$ : white pp.

**Ethyl-imide**  $\text{C}_6\text{H}_5(\text{OMe})_2\langle\text{CO}\rangle\text{NEt}$  (?). [98°]. Formed by heating the potassium derivative of the imide with  $\text{EtI}$ , or by distilling ethylamine hemipate. Needles (from water); v. e. sol. alcohol and ether (L.).

**Iso-imide**  $\text{C}_6\text{H}_5\text{NO}_4$ . [above  $320^\circ$ ]. Formed, together with other bodies, by oxidising papaverine with  $\text{KMnO}_4$  (Goldschmidt, *M.* 8, 512). Small needles (from water). May be sublimed. V. sl. sol. hot water, alcohol, and ether, m. sol. hot  $\text{HOAc}$ . The alcoholic solution exhibits blue fluorescence. Boiling  $\text{KOH}$  splits it up into  $\text{NH}_3$  and hemipic acid.

**Ethyl-iso-imide**  $\text{C}_6\text{H}_5\text{E:NO}_4$ . [227°]. Formed by oxidising papaverine ethyl-bromide with  $\text{KMnO}_4$  (G.). Needles (from alcohol); sl. sol. boiling alcohol; sublines in colourless needles. Potash converts it into ethyl-hemipamic acid  $\text{C}_6\text{H}_5(\text{OMe})_2(\text{CO}_2\text{H})(\text{CONHEt})$  which resembles the corresponding benzyl derivative.

**Benzyl-iso-imide**  $\text{C}_6\text{H}_5(\text{CH}_2\text{Ph})\text{NO}_4$ . [225°]. Formed, together with other products, by oxidising papaverine benzyl-chloride (30 g.)

with 2 p.c. aqueous  $\text{KMnO}_4$  (100 g.) (Goldschmidt, *M.* 9, 327). Needles (from alcohol). May be sublimed. Neutral; insol. dilute acids and alkalis. Split up by boiling  $\text{KOH}$  into hemipic acid and benzylamine, an intermediate product being the mono-benzylamide of hemipic acid  $\text{C}_6\text{H}_5(\text{OMe})_2(\text{CO}_2\text{H})(\text{CONHC}_6\text{H}_5)$ , which crystallises from alcohol in very slender needles, reconverted by heat into the imide. The mono-benzylamide is v. sol. aqueous alkalis; its  $\text{K}$  salt crystallises in needles, v. sol. water; its  $\text{Ag}$  salt is amorphous; the  $\text{Ca}$  salt,  $\text{CaA}'$ , crystallises in small needles, m. sol. water.

**Nitro-hemipic acid**  $\text{C}_6\text{H}(\text{NO}_2)(\text{OMe})_2(\text{CO}_2\text{H})$ . [166°].

**Formation**.—1. By boiling nitro-opianic acid with  $\text{HNO}_3$  (4 pts.) (Liebermann, *B.* 19, 2285; Grüne, *B.* 19, 2303).—2. Together with nitro-pseudo-mecconine, by heating mecconine or pseudo-mecconine (1 g.) with  $\text{HNO}_3$  (10 c.c. of S.G. 1.14) for 1 hour at  $160^\circ$  (Salomon, *B.* 20, 888).

**Preparation**.—When opianic acid is nitrated by  $\text{HNO}_3$  and the solid cake produced crystallised from water, nitro-opianic acid separates and nitro-hemipic acid remains in the mother liquor. Nitro-hemipic acid is obtained in larger quantity by heating opianic acid (50 g.) with  $\text{HNO}_3$  (50 g.) as long as red fumes come off. The mass is crystallised from water and the mother liquor mixed with  $\text{NH}_3$  and  $\text{BaCl}_2$ . Baric nitro-hemipate separates. The free acid is got by decomposing this with  $\text{H}_2\text{SO}_4$  (Prinz, *J. pr.* [2] 24, 859).

**Properties**.—Yellow prisms (containing aq). Salts.— $\text{A}''\text{K}$ : yellow prisms, v. sol. water and alcohol.— $\text{A}''\text{Ag}$ : yellow pp.

**Anhydride**  $\text{C}_6\text{H}(\text{NO}_2)(\text{OMe})_2\langle\text{CO}\rangle\text{O}$ :

[145°]; thick yellow prisms; formed by heating the acid to  $160^\circ$ – $165^\circ$  (Liebermann, *B.* 19, 2285; Grüne, *B.* 19, 2303).

**o-Amido-hemipic acid**  $\text{C}_6\text{H}_3\text{O}_5\text{N}$  &c.  $\text{C}_6\text{H}(\text{OMe})_2(\text{NH}_2)(\text{CO}_2\text{H})$ . **Amido-di-methoxy-phthalic acid**. The free acid was not isolated as its solution easily decomposes on evaporation.

**Formation**.—1. By reduction of nitro-hemipic acid with  $\text{FeSO}_4$  and  $\text{NaOH}$ .—2. By boiling the anhydro-acid (so-called 'azo-opianic acid')

$\text{C}_6\text{H}(\text{OMe})_2(\text{CO}_2\text{H})\langle\text{COH}\rangle\text{N}$  with excess of baryta-water.

**Reaction**.—By diazotisation and boiling with alcohol it may be converted into hemipic acid,  $\text{C}_6\text{H}_5(\text{OMe})_2(\text{CO}_2\text{H})$ .

**Salts**.— $\text{A}''\text{Na}$ , 8aq: easily soluble long white needles.— $\text{A}''\text{Ba}$ : glistening golden-yellow spangles, sl. sol. water.— $\text{A}''\text{Cu}$ , 7aq: slender green needles.— $\text{A}''\text{Ag}$ : yellowish-white pp. (Grüne, *B.* 19, 2301).

**Acetyl derivative**  $\text{C}_6\text{H}(\text{OMe})_2(\text{NHAc})(\text{CO}_2\text{H})$ : [160°–170°]; colourless needles containing aq. Heated to  $125^\circ$  it is converted by elimination of water into the acetyl derivative of the anhydro-acid (Liebermann, *B.* 19, 2921).

Anhydro-*o*-amido-hempic acid (so-called *aso-opianic acid*)  $C_{10}H_8O_4N$  i.e.

[200°]. Formed by boiling nitro-opianic acid with  $SnCl_4$  and  $HCl$  (Prinz, *J. pr.* [2] 24, 364). Long white slender needles (from hot water). Decomposed on fusion. It dissolves in conc.  $H_2SO_4$  and is thrown down unaltered by water. It is not affected by sodium-amalgam, or by  $KMnO_4$  in presence of  $H_2SO_4$ . By boiling with baryta water it is converted into amido-hempic acid  $C_6H(OMe)_2(NH_2)(CO_2H)_2$  (Liebermann, *B. 19*, 2275; Grüne, *B. 19*, 2299).

Salts.—A'K: white crystalline powder.—A'Ag: white pp.—BaA',  $CaA'$ : slender needles.

Methyl ether A'Me: [127°].

Ethyl ether A'Et: [98°]; needles, sol. alcohol, ether, &c.

Phenyl hydrazide

yellow tetragonal pyramids,  $a:b = 1.0:5.947$ .

Acetyl derivative

needles. Formed by acetylation of the anhydro-acid; by heating amido-hempic acid with  $Ac_2O$  and  $NaAc$ ; or by heating acetyl-amido-hempic acid to 125°. By warming with aqueous alkalis it is converted into acetyl-amido-hempic acid (Liebermann, *B. 19*, 2920).

Propionyl derivative  $C_{10}H_8(C_2H_3O)_2N$ : [189°].

Iso-hempic acid  $C_6H_2(OMe)_2(CO_2H)_2[5:4:3:1]$ . [246°]. Formed by oxidising iso-opianic acid with a dilute solution of  $KMnO_4$  (Tiemann & Mendelssohn, *B. 10*, 398). White needles (from hot water); nearly insol. cold water, v. sol. alcohol and ether. May be sublimed. The salts of the alkalis and alkaline earths are easily soluble and crystallise well.

Mono-methyl ether MeHA". [167°].

Nor-methyl-hempic acid v. Methyl derivative of Di-oxy-PTHALIC ACID.

Nor-methyl-nitro-hempic acid v. Methyl derivative of Nitro-Di-oxy-PTHALIC ACID.

Nor-methyl-anhydro-amido-hempic acid v. Methyl derivative of Anhydro-Di-oxy-Amido-PTHALIC ACID.

**HEMP.** *Cannabis sativa*. Hemp-seeds contain about 25 p.c. of a drying oil, S.G. 1.2-1.28, which on saponification yields an acid  $C_{11}H_{19}O_2$ . When this acid is dissolved in  $HOAc$  and treated with bromine there is formed  $C_{11}H_{17}BrO_2$  [115°] and  $C_{11}H_{15}Br_2O_2$  [177°]. The acid  $C_{11}H_{19}O_2$  yields on oxidation sativic acid  $C_{11}H_{17}(OH)O_2$  (Hazura, *M. 8*, 147). Hemp leaves yield on distillation an essential oil  $C_{11}H_{19}$  (257°), V.D. 7-1, S.G. 0.93,  $[n]_D^{20} = -10.8^\circ$  at 25.5° (Valente, *G. 10*, 479; 11, 196).

Indian Hemp v. CANNABIS INDICA.

**HENDECANAPHTHENE** v. HENDECYLENE.

**n-HENDECANE**  $C_{11}H_{24}$ . [-26.5°]. (195°). S.G. 0.7559;  $d_4^{20}$  0.816. Formed by the action of  $HI$  and phosphorus at 230° upon hendecic

VOL. II.

(undecylic) acid, or upon  $C_{11}H_{23}Cl$  obtained by treating oil of rue with  $PCl_5$  (Krafft, *B. 15*, 1697).

**HENDECENOIC ACID**  $C_{11}H_{18}O_2$  i.e.

$CH_3 \cdot CH(CH_2)_9 \cdot CO_2H$  (?). *Undecylenic acid*. [24.5°]. (165° at 15 mm.) (B.); (275° at 760 mm.); (199° at 90 mm.) (K.). Formed by distilling castor oil under diminished pressure (Krafft, *B. 10*, 2035; Brunner, *B. 19*, 2228). Large plates; distils with decomposition at 275°. Split up by potash-fusion into acetic acid and *n*-ennoic acid  $C_9H_{16}O_2$ . Fuming  $HNO_3$  oxidises it to sebacio acid  $C_{10}H_{16}O_4$ . With bromine it forms  $C_{11}H_{17}BrO_2$  [38°].  $HBr$  forms  $C_{11}H_{21}BrO_2$  [35°].  $HI$  gives  $C_{11}H_{23}IO_2$  [24°].— $BaA_2$ : flat needles or laminae, S. -098 at 15.5° (Becker, *B. 11*, 1412).

Di-hendecenoic acid  $(C_{11}H_{18}O_2)_2$  i.e.

$C_{11}H_{18} \cdot CO \cdot O \cdot C_{11}H_{18} \cdot CO_2H$ . *Diundecylenic acid*. [30°]. (275° at 15 mm.). Formed, together with the following acid, by heating the preceding acid in a sealed tube above 300° (Krafft & Becker, *B. 10*, 2044; 11, 1412; Krafft & Brunner, *B. 17*, 2986). Formed also by the action of silver hendecenoate on iodo-hendecenoic acid (Brunner, *B. 19*, 2224). Crystallises from dilute alcohol. On heating with  $KOH$  hendecenoic acid is among the products.  $Br$  forms  $C_{22}H_{38}Br_2O_4$ , an almost colourless oil.

**Poly-hendecenoic acid**  $(C_{11}H_{18}O_2)_x$ . *Polyundecylenic acid*. Formed as above, and also found in the residue after distilling castor oil. Amorphous. Gives ennoic acid on fusion with potash, and sebacio acid on treatment with  $HNO_3$ .

**Hendecenoic acid**  $C_{11}H_{18}O_2$ . *Petroleum acid*. (250°-260°). S.G. 0.982;  $d_4^{20}$  0.909. Occurs in petroleum (Hell & Medinger, *B. 7*, 1217; 10, 451; Markownikoff & Ogloblin, *J. R. 15*, 345). Extracted from rectified petroleum by aqueous alkalis, and p.p.d. by  $H_2SO_4$ . Liquid. Not affected by potash-fusion or by nitrous acid. Does not combine with bromine. Boiling  $HNO_3$  (S.G. 1.3) forms acetic acid and an acid  $C_9H_{16}O_4$ .— $AgA'$ : flocculent pp.

Methyl ether MeA'. (236°-240°) at 739 mm. S.G. 0.939;  $d_4^{20}$  0.919.

**HENDECINENE**  $C_{11}H_{20}$ . *Rutylidene*. (c.200°)

(Giesecke, *Z. 1870*, 431); (210°-215°) (Bruylants, *B. 8*, 413). Formed by the action of alcoholic  $KOH$  at 130° on  $C_{11}H_{23}Cl$ , obtained from  $C_{11}H_{23} \cdot CO \cdot CH_2$  (in oil of rue) and  $PCl_5$ . Liquid. Gives a white pp. with ammoniacal  $AgNO_3$  and a brownish-yellow pp. with ammoniacal  $CuCl_2$ .

**HENDECINOIC ACID**  $C_{11}H_{18}O_4$ . *Undecolic acid*. [59.6°].

From the difluoride of hendecenoic (undecylenic acid)  $C_{11}H_{18}Br_2O_2$  and alcoholic  $KOH$  (Krafft, *B. 11*, 1414). Thin laminae; decomposed on distillation. V. sl. sol. water, v. sol. alcohol. Fuming  $HNO_3$  oxidises it to arachic acid  $C_{19}H_{38}O_2$ .

Salts.— $CaA_2$  aq.— $BaA_2$ . S. 47 at 15.5°  $AgA'$ .

**Hendecinoic acid**  $C_{11}H_{18}O_4$ . (270°-280°).

Among the products obtained by passing  $CO$  at 160° over a mixture of sodium isovalerate and sodium ethylate (Loegg, *A. 202*, 321). Liquid.

**HENDECOLIC ACID**  $C_{11}H_{18}O_3$ . *Undecylic acid*. [28.5°]. (228° at 160 mm.).

Formed by heating hendecenoic acid (undecylenic acid) with  $HIAg$  and red phosphorus at 210°. Formed also by oxidising methyl hendecyl ketone  $Me \cdot CO \cdot C_{11}H_{23}$  with chromic acid mixture (Krafft, X X

B. 11, 2219; 12, 1667). Crystalline mass. insol. water, v. e. sol. alcohol, sol. ether.— $3\text{NaA}'$ .— $\text{AgA}'$ .

HenDecoic acid  $\text{C}_{11}\text{H}_{22}\text{O}_2$  i.e.  $\text{Me}_2\text{C}(\text{CH}_2)_9\text{CO}_2\text{H}$ . *Methyl 3i-tert-butyl-acetic acid*. [66°–70°]. (266° cor.). Formed by oxidizing tri-iso-butylene with chromic acid mixture (Butlerow, J. R. 11, 203). Crystalline mass. insol. water, v. e. sol. alcohol and ether.— $\text{NaA}'$  tag: crystalline. Absorbs  $\text{CO}_2$  from the air, the acid being liberated.—Magnesium salt: v. sl. sol. cold water.

*Methyl ether*  $\text{MeA}'$ . (217°–220°).

*Ethyl ether*  $\text{EtA}'$ . (225°–230°).

HenDecoic acid  $\text{C}_{11}\text{H}_{22}\text{O}_2$ . *Umbellulic acid*. [c. 28°]. (275°–280° cor.). The glyceryl derivative of this acid constitutes the greater part of the fatty substance in the kernels of the Californian laurel (*Umbellularia californica*) (Stillman a. O'Neill, Am. 4, 206). Crystalline.— $\text{AgA}'$ .

*Methyl ether*  $\text{MeA}'$ . (245°).

*Ethyl ether*  $\text{EtA}'$ . (254°).

*Isoamyl ether*  $\text{C}_5\text{H}_{11}\text{A}'$ . (295°).

HENDECONENE  $\text{C}_{11}\text{H}_{20}$ . (182°). Occurs, together with the following, in Dippel's animal oil (Weidel a. Ciamician, B. 13, 80). Does not combine with  $\text{HCl}$ .

HenDecoene  $\text{C}_{11}\text{H}_{20}$ . (203°). V. supra.

HenDecoene ( $\text{C}_{11}\text{H}_{20}$ ). [196°]. Extracted by ether from *Cascara amara* and *Phlox carolina* (Abbot, B. 21, 2593). Needles, sol. ether,  $\text{HOAc}$ , chloroform, hot alcohol, petroleum ether, and  $\text{Ac}_2\text{O}$ .

HENDECYL ALCOHOL  $\text{C}_{11}\text{H}_{24}\text{O}$  i.e.  $\text{C}_{10}\text{H}_{21}\text{CH}(\text{OH})\text{CH}_3$ . (229°). S.G. 12–827. From oil of rue by reduction with sodium amalgam (Giesecke, Z. 1870, 428).

HenDecyl alcohol  $\text{C}_{11}\text{H}_{24}\text{O}$ . (245°–255°). A product of the action of sodium on isoamyl isovalerate (Lourengo a. Aguiar, Z. 1870, 404).

HENDECYL BROMIDE  $\text{C}_{11}\text{H}_{23}\text{Br}$  i.e.  $\text{C}_{10}\text{H}_{21}\text{CH}_2\text{Br}$ . From the corresponding alcohol (v. supra),  $\text{Br}$ , and  $\text{Z}$  (Giesecke). Splits up on distillation into  $\text{HBr}$  and hendecylene  $\text{C}_{11}\text{H}_{22}$ .

HENDECYL CHLORIDE  $\text{C}_{11}\text{H}_{23}\text{Cl}$ . (220°–224°). Formed by chlorinating the hendecane in petroleum (Pelouze a. Cahours, A. Ch. [4] 1, 5).

HENDECYLENE  $\text{C}_{11}\text{H}_{22}$ . *Undecylene*. (193°). Formed by distilling hendecyl bromide (Giesecke).

HenDecylene  $\text{C}_{11}\text{H}_{22}$ . (195° cor.). S.G. 2–791. Occurs among the products of the distillation of the lime salts obtained by saponifying train oil (Warren a. Storer, Z. 1868, 230).

HenDecylene  $\text{C}_{11}\text{H}_{22}$ . (196° cor.). S.G. 2–840. Occurs in Burmese petroleum (W. a. S.).

HenDecylene  $\text{C}_{11}\text{H}_{22}$ . (194°). A product of the action of heat on paraffin (Torpe a. Young, A. 1855, 23).

HenDecylène  $\text{C}_{11}\text{H}_{22}$ . *HenDecanaphthene*. (180°). S.G. 9–812. Occurs in petroleum from Baku (Markownikoff a. Ogloblin, J. R. 15, 335). On chlorination it gives a mixture (210°–225°) of chlorides  $\text{C}_{11}\text{H}_{21}\text{Cl}$ , whereas alcoholic  $\text{KOH}$  forms hydrocarbons  $\text{C}_{11}\text{H}_{20}$ , which combine directly with  $\text{Br}$  and  $\text{H}_2\text{SO}_4$  but do not ppt. ammoniacal  $\text{AgNO}_3$ .

HENICOSANE  $\text{C}_{12}\text{H}_{26}$ . [40°]. (215° at 15 mm.). S.G. 2–778; 2–74. Formed by reduction of the dichloride ( $\text{C}_{12}\text{H}_{24}$ ) $_2\text{CCl}_2$  of the ka-

tone ( $\text{C}_{12}\text{H}_{24}$ ) $_2\text{CO}$ , obtained by the dry distillation of barium hendecenoate (Kraft, B. 15, 1718). Obtained also from brown coal paraffin by fractional distillation (Kraft, B. 21, 2263). Silvery plates.

HENICOSENOIC ALDEHYDE  $\text{C}_{12}\text{H}_{24}\text{O}$  i.e.

*Di-heptyl-heptoic aldehyde*. (c. 320°) at 800 mm. S.G. 15–874. Formed by the action of sodium amalgam on heptoic aldehyde; the yield being 5 to 10 p.c. (Perkin, jun., C. J. 43, 71). Slightly yellow oil; sol.  $\text{CS}_2$ . Reduces ammoniacal silver solution. Does not appear to combine with  $\text{NaHSO}_4$ . Combines with bromine (1 mol.) in  $\text{CCl}_4$ . Decomposed by boiling with dilute  $\text{H}_2\text{SO}_4$ . Blackens when heated with potash.

*n*-HENTRIACONANE  $\text{C}_{11}\text{H}_{24}$ . [68°]. (302° at 15 mm.). S.G. 2–773; 2–762. Occurs in bee's wax (Schwalb, A. 235, 106). Formed by reduction of the dichloride ( $\text{C}_{11}\text{H}_{24}$ ) $_2\text{CCl}_2$  of palmitone ( $\text{C}_{16}\text{H}_{34}$ ) $_2\text{CO}$  with  $\text{HI}$  and  $\text{P}$  (Kraft, B. 15, 1714). Sl. sol. ether.

HEPTACOSANE v. HEPTACOSANE.

*n*-HEPTADECANE  $\text{C}_{17}\text{H}_{36}$ . [23°]. (163° at 10 mm.); (223° at 100 mm.); (303° at 760 mm.). S.G. 25–775; 25–771; 25–724. Hexagonal tables. Formed by reduction of the dichloride of methyl hexadecyl ketone, or of margaric acid with  $\text{P}$  and  $\text{HI}$  (Kraft, B. 15, 1702). Occurs in crystalline commercial sealy paraffin (Kraft, B. 21, 2256).

HENDECOIC ACID v. MARGARIC ACID.

HEPTADECYLAMINE  $\text{C}_{17}\text{H}_{35}\text{NH}_2$ . [49°]. (335°–340°). Formed by distilling stearyl-heptadecyl-urea  $\text{C}_{17}\text{H}_{35}\text{O.NH.CO.NH.C}_{17}\text{H}_{35}$  with lime (Hotmann, B. 15, 774; Turpin, B. 21, 2486). Fatty crystalline mass, sol. alcohol and ether. Absorbs moisture and  $\text{CO}_2$  from the air. Not volatile with steam. Its ethereal solution evaporated with  $\text{CS}_2$  forms  $\text{C}_{17}\text{H}_{35}\text{NH}_2$ . S.CS.NHC,  $\text{H}_{17}$ , [90°], which on boiling with alcohol forms di-heptadecyl-thio-urea [94°]. The hydrochloride is insol. water, and crystallises from alcohol in plates with a fatty lustre.  $-\text{B}_2\text{H}_6\text{PtCl}_6$  minute yellow crystals.

*Benzoyl derivative*  $\text{C}_{17}\text{H}_{35}\text{NHBz}$ . [91°]. Crystallises from benzene in plates.

HEPTADECYL-CARBAMIC ETHER

$\text{C}_{17}\text{H}_{35}\text{NH.CO.Et}$ . [62°]. Formed by the action of boiling alcohol on heptadecyl cyanate  $\text{C}_{17}\text{H}_{35}\text{N:CO}$ , an oil which is obtained by heating heptadecylamine hydrochloride with  $\text{COCl}_2$  in benzene at 100° (Turpin, B. 21, 2486). Lustrous plates.

DI-HEPTADECYL KETONE ( $\text{C}_{17}\text{H}_{35}$ ) $_2\text{CO}$ . [88°]. One of the products obtained by distilling stearyl-heptadecyl-urea with lime (Turpin, B. 21, 2487). Sl. sol. alcohol.

HEPTADECYL THIOCARBIMIDE

$\text{C}_{17}\text{H}_{35}\text{NCS}$ . [32°]. Formed, together with a small amount of di-heptadecyl-thio-urea, when heptadecylamine is heated with alcohol and  $\text{CS}_2$  at 100° (Turpin, B. 21, 2486). V. sol. alcohol and ether. Cannot be distilled.

HEPTADECYL-THIO-UREA

$\text{C}_{17}\text{H}_{35}\text{NH.CO.SNH}_2$ . [111°]. From the preceding and alcoholic  $\text{NH}_3$  at 100° (T.). Sl. sol. alcohol.

Di-heptadecyl-thio-urea ( $\text{C}_{17}\text{H}_{35}\text{NH}$ ) $_2\text{CS}$ . [94°]. From heptadecylamine by boiling with alcoholic  $\text{CS}_2$ .

**HEPTADECYL-UREA**  $C_{17}H_{35}NH.CO.NH_2$ . [109°]. From heptadecylamine hydrochloride and alcoholic potassium cyanate (Turpin, *B.* 21, 2486). Sol. alcohol.

**Stearyl derivative**  $C_{17}H_{35}NH.CO.NH.C_{18}H_{37}O_2$ . [112°]. Formed by the action of bromine and NaOH on the amide of stearic acid. Pearly laminae (Hofmann, *B.* 15, 761).

**Di-heptadecyl-urea**  $(C_{17}H_{35}NH).CO$ . [73°]. From di-heptadecyl-thio-urea and  $HgO$ .

**n-HEPTAICOSANE**  $C_{71}H_{142}$ . [60°], [270° at 15 mm.]. S.G.  $\frac{8}{15}$  779;  $\frac{15}{15}$  754. Formed by reduction of the dichloride of myristone  $(C_{13}H_{26})_2CO$  with HI and P (Krafft, *B.* 15, 1713). Appears also to be present in bee's wax (Schwalb, *A.* 235, 106). Occurs also in commercial paraffin (Krafft, *B.* 21, 2264).

**HEPTANAPHTHENE**  $C_{14}H_{12}$ . (101°). A hydrocarbon in Caucasian petroleum (Milkowsky, *Bl.* [2] 45, 182).

**n-HEPTANE**  $C_7H_{16}$ , i.e.  $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.CH_3$ . *Heptyl hydride*. *Methyl-hexane*. *Ethyl-amyl*. *Di-propyl-methane*. *Abietene*. Mol. w. 100. (98-43°) (Thorpe); (98-4° cor.) (Perkin, *C. J.* 45, 447). S.G.  $\frac{15}{15}$  7005 (T.);  $\frac{15}{15}$  6885;  $\frac{25}{25}$  6814. M.M. 7-669 at 14-1°. C.E. (0°-10°) 001222; (0°-100°) 001439 (T.). H.C. 1137450 (Longunine, *C. R.* 93, 274). S.V. 162-56 (T.); 165-0 (Ramsay). V.D. 50-0 (Theory 49-9).  $\mu_D = 1-3879$ .  $n_D = 56-4$  (calc. 55-8). Coefficient of viscosity: 004236 at 15-3°. Angle of capillarity 167° (Thorpe). Critical temperature, 281° (Thorpe a. Rücker, *C. J.* 45, 165). Occurs almost absolutely pure in the exudation of the nut pine (*Pinus sabiniana*) (Thorpe, *C. J.* 35, 296; 37, 213; cf. Wenzell, *Ph.* [3] 2, 789). Occurs also in American petroleum, in coal-tar oil (Pelouze a. Cahours, *C. R.* 56, 505; Warren, *J.* 1865, 516; Schorlemmer, *C. J.* 15, 423; 26, 319; *Pr.* 14, 164, 464), and in Galician petroleum (Lachowicz, *A.* 220, 193). Formed by distilling azelaic acid with baryta (Dale, *C. J.* 17, 253). Occurs, together with heptylene, amongst the hydrocarbons obtained by distilling the lime-soap of Menhaden oil (Warren a. Storer, *Z.* [2] 4, 231). Obtained also by distilling triolein under pressure (Engler, *B.* 22, 596). Treated with chlorine heptane gives a mixture of chloroheptanes (143°-158°). These may be converted into a mixture of a primary heptyl alcohol (165°-170°) and a secondary heptyl alcohol (156°-158°). By oxidising with chromic-mixture the former gives heptioic acid, the latter methyl amyl ketone and, by further oxidation, valeric and acetic acids; hence the alcohols are:

- $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.OH$  and  $CH_3.CH_2.CH_2.CH_2.CH_2.CH(OH).CH_3$ , (Schorlemmer a. Thorpe, *T.* 174, 270; *A.* 217, 150). The mixture of chlorides (143°-157-5°) is converted by alcoholic potash partly into heptylene (98-5°), partly into a mixture of ethyl heptyl oxides. The heptylene gives on oxidation valeric and acetic acids, hence it is  $C_7H_{14}.OH.CH_2.CH_3$ . Liquid bromine acting upon hot n-heptane forms chiefly secondary heptyl bromide; gaseous bromine forms primary and secondary heptyl bromides in about equal quantities. Liquid Br dissolved in cold heptane forms chiefly di-bromo-heptanes (Venable, *Am.* 10, 237).

**Heptane**  $Me.CH.CH_2.Et$ . **Methyl-isoamyl**. (90-35°) (Thorpe, *C. J.* 37, 216). S.G.  $\frac{2}{2}$  69692 (T.);  $\frac{15}{15}$  6833 (G.). C.E. (0°-10°) 001253; (0°-50°) 0013318; S.V. 161-98. V.D. 3-45 (calc. 3-47). A product of the distillation of whale oil under pressure (Engler, *B.* 22, 595). Formed by the action of sodium (14 pts.) on a mixture of  $EtI$  (60 pts.) and iso-amyl iodide (70 pts.) (Wurtz, *A. Ch.* [3] 44, 275). Formed also by gradually adding sodium to a mixture of ethyl and isoamyl bromides at 25°, then heating for a few hours at 100° and fractionally distilling (Grimshaw, *C. J.* 26, 809). Obtained also from  $CH_3.CH(OH).CH_2.CH_2.CHMe$  by successive treatment with HI and with Zn and HCl (Purdie, *C. J.* 39, 467). According to Berthelot (*Bl.* [2] 9, 455) phthalic and terephthalic acid heated with (80 pts.) saturated  $HIAq$  yield a heptane (91°-93°); Berthelot also obtained by this treatment heptanes from toluene and from o- and p-toluidine (*C. R.* 68, 606).

**Heptane**  $CMeEtPrH$ . **Methyl-ethyl-propyl-methane**. (91°). S.G.  $\frac{23}{23}$  6895. [a] +2-70 for 100 mm. From active amyl iodide, propyl iodide and sodium (Just, *A.* 220, 153).

**Heptane**  $CH_3Et$ . **Tri-ethyl-methane**. (96°). V.D. 101-5. S.G.  $\frac{21}{21}$  680. Formed by the action of  $ZnEt_2$  and sodium upon orthoformic ether (Ladenburg, *B.* 5, 752). Colourless liquid.

**Heptane**  $CMe_2Et_2$ . (87°). S.G.  $\frac{2}{2}$  7111;  $\frac{23}{23}$  6958. Formed by the action of  $ZnEt_2$  upon  $CH_3.CCl_2.CH_3$  (from acetone), the distillate being mixed with water and fractionally distilled (Friedel a. Ladenburg, *A.* 142, 810). Besides n-heptane, Pennsylvanian petroleum contains a heptane (90°). S.G.  $\frac{15}{15}$  709 which is either  $CMe_2Et_2$  or  $CHMeEtPr$  for it gives on oxidation a ketone  $C_7H_{14}O$  (142°-146°) which on further oxidation yields nothing but acetic acid (Schorlemmer, *C. J.* 26, 319). The heptane in question gives rise to a mixture of heptyl chlorides (144°-158°), to a heptylene (90°-92°), to a primary heptyl alcohol (165°-170°), to a secondary heptyl alcohol (148°-150°), and to a heptioic acid (209°-213°).

**References.** — Di-BROMO- and Di-CHLORO-HEPTANE.

#### HEPTANE PHOSPHONIC ACID

$C_7H_{15}.CH_2.PO(OH)_2$ . [106°]. Formed by heating oxy-heptane phosphonic acid  $C_7H_{15}.CH(OH).PO(OH)_2$  with conc.  $HIAq$  at 200° (Fossek, *M.* 7, 29). Swells up in a little water, forming a jelly. Sol. alcohol, ether, and ligroin.

**Oxy-heptane phosphonic acid**  $C_7H_{15}.CH(OH).PO(OH)_2$ . [185°]. From enanthol by successive treatment with  $PCl_3$  and water (Zepharovitch, *M.* 7, 28). Tables.

**n-HEPTANE SULPHONIC ACID**  $C_7H_{15}.SO_3H$  (Winssinger, *Bull. Acad. Belg.* [3] 11, 12). Is converted by chlorine into a chloro-derivative of which the Ba salt is  $(C_7H_{13}.ClSO_3)_2Ba$ . A tri-chloro-sulphonic acid is also formed.  $ICl_3$  yields two compounds, the one insoluble in water is  $C_7H_{13}.Cl_3O_3$ , and the other is  $C_7H_{13}.Cl_2O_3$ . The Ba salts of these acids crystallise out together forming crystals which on analysis correspond to the formula

(Spring a. Winssinger, *Bl.* [2] 49, 68).

#### HEPTENE v. HEPTYLENE.

## HEPTENOIC ACID.

**HEPTENOIC ACID**  $C_7H_{12}O_2$ , *Tetracrylic acid*. (218° i. v.). Formed by the dry distillation of turpenylic acid  $C_{10}H_{16}O$  (Fittig & Kraft, A. 208, 79). Liquid, smelling like valeric acid; lighter than water. Sol. water. Gives acetic acid than water. Combines with HBr forming  $C_7H_{11}BrO$ , which, on standing, changes to the anhydride of oxy-heptenoic acid. Combines with bromine.— $CaA'$ , 5aq: needles or prisms, v. sol. water.— $AgA'$ : small needles (from water).

*Ethyl ether EtA'*. (190°). (Amthor, *Ar. Ph.* [3] 18, 536).

Heptenoic acid  $Pr.CH_2.CH:CH.CO.H$ . Formed by heating isovaleric aldehyde with HOAc and NaOAc (Fittig, B. 16, 1438). Liquid, volatile with steam.

Heptenoic acid  $Pr.CH:CH.CO.H$ . (225°). Formed, together with the lactone of oxy-heptenoic acid, by heating propyl-paraconic acid (the lactone of oxy-butyl-succinic acid) (Fittig, B. 20, 3179).

*Reference*.—CHLORO-HEPTENOIC ACID.

**HEPTENYL BROMIDE**  $C_7H_{13}Br$ . (165°). Formed by the action of alcoholic KOH on di-bromo-heptane derived from emanthol and  $PBr_3$  (Rubien, A. 142, 294; B. 8, 409).

**HEPTENYL CHLORIDE**  $C_7H_{13}Cl$ . *Chloro-emanthylene*. *Chloro-heptylene*. (155° cor.). From di-chloro-heptane (emanthylene chloride)  $C_7H_{12}Cl_2$  and alcoholic KOH (Limpricht, A. 103, 82). Heated with alcoholic KOH it yields  $C_7H_{12}$  which forms with alcoholic  $AgNO_3$  a pp.  $C_7H_7AgAgNO_3$  (Béhal, *Bl.* [2] 49, 581).

Heptenyl chloride  $C_7H_{13}Cl$ . (141°). From di-propyl ketone and  $PCl_5$  (Tavildaroff, B. 9, 1442).

Heptenyl chloride  $C_7H_{13}Cl$ . (119°). S.G. 951. From di-isopropyl ketone and  $PCl_5$  (Henry, B. 8, 400). Alcoholic KOH converts it into tetra-methyl-allylene (70°).

Heptenyl chloride  $C_7H_{13}Cl$ . (55° in *vacuo*). From the heptene derived from perseite and HCl (Maquenne, C. 4, 108, 101). Crystalline. Does not combine with Br. Potash reproduces the heptene.

**HEPTIC ACID** (so called)  $C_7H_{12}O_3$  (Pawloff, C. R. 97, 99);  $C_7H_{10}O_3$ , i.e.  $CH_2.CO.C(CO.H).C_2H_5$  (Demarcay). (151°). One of the products of the action of alcoholic KOH on bromo-isobutyl aceto-acetic ether (Demarcay, C. R. 86, 1135). Flat needles (from water); sol. chloroform, sl. sol. cold water. Colours  $FeCl_3$  pale brown. Decomposes carbonates only on heating.

**HEPTINENE**  $C_7H_{12}$ , i.e.  $Pr.CH_2.CH_2.CiCH$ . *Emanthylidene*. *Heptene*. *Amyl-acetylene*.

Formed by (107°) (B.); (102°) (B.). S.G. 7508. Formed by boiling di-chloro-heptane  $Pr.CH_2.CH_2.CHCl_2$  with alcoholic KOH and heating the resulting with alcoholic KOH with alcoholic KOH at 150°.—Heptenyl chloride  $C_7H_{13}Cl$  (Limpricht, A. 103, 84; Rubien, A. 142, 294). (141°). Sol. alcohol and ether. Bromine acts violently upon it, forming  $C_7H_{11}Br_2$  and  $C_7H_{11}Br$ , Ammoniacal  $AgNO_3$  gives a white pp.; ammoniacal  $Cu_2Cl_2$  forms a yellow pp. (Bruylants, Z. 8, 409). An alcoholic solution of  $AgNO_3$  gives a pp. of  $C_7H_{11}Ag_2NO_3$ , sol. excess of the precipitant (Béhal, *Bl.* [2] 49, 335). When heated for 86 hours at 145° with alcoholic KOH in a sealed tube it changes to methyl-butyl-acetylene  $C_7H_{12}O$  (Béhal, A. Ch. [6] 15, 428). When

dissolved in excess of  $H_2SO_4$  and distilled with water it gives methyl amyl ketone  $C_7H_{14}O$  (Béhal, A. Ch. [6] 15, 270).

Heptene  $C_7H_{12}$ . (104°). S.G. 22 803. From the product of distillation of rosin (Tilden, B. 13, 1605; Renard, C. R. 91, 419; Morris, C. J. 41, 173). Occurs also among the products of the action of boiling HIAq upon perseite (Maquenne, C. R. 107, 588; 108, 101). Liquid, not precipitated by ammoniacal  $AgNO_3$ .

*Reactions*.—1. Absorbs oxygen readily. Thus in 10 days it absorbs 100 volumes of oxygen, and if the product be distilled crystalline  $C_7H_{12}O_2$  is got.—2.  $H_2SO_4$  converts it into di-heptene  $C_7H_{12}$  (246°); V.D. 542.—3.  $HNO_3$  (S.G. 1.8) forms a little di-nitro-heptene  $C_7H_{12}(NO_2)_2$  (q. v.).  $CO_2$  forms, acetic, butyric, and succinic acids.—4.  $K_2Cr_2O_7$  and  $H_2SO_4$  give  $CO_2$  and acetic acid.—5. Forms two bromides,  $C_7H_{12}Br_2$  and  $C_7H_{11}Br$ .—6. When heated to a dull red heat it gives pentene, hexene (72°), benzene, toluene, and hydrogen, the two last named being the chief products (Renard, C. R. 104, 574).—7. Conc. HIAq forms, even in the cold, crystalline  $C_7H_{11}I$ .—8. Conc. HClAq at 150° forms crystalline  $C_7H_{11}Cl$  which boils in *vacuo* at 55°.

*Constitution*.— $McCH:C:CHPr$  would give butyric and acetic acids on oxidation. Maquenne, however, considers the hydrocarbon to contain a tetra-methylene nucleus.

Heptene  $C_7H_{12}$ , i.e.  $CH_3.CiC.C_2H_5$ . *Methyl-butyl-acetylene*. (113°). S.G. 2 763. Formed by heating  $C_7H_{11}Cl$  with alcoholic KOH at 150° (Béhal, A. Ch. [6] 15, 428). Liquid. Gives no pp. with ammoniacal  $Cu_2Cl_2$  with ammoniacal  $AgNO_3$ , or with alcoholic  $AgNO_3$ . Gives a ketone on hydration. Forms a compound with  $HgCl_2$ .

Heptene  $C_7H_{12}$ , i.e.  $Et.CiC.C_2H_5$ . *Ethyl-propyl-acetylene*. (106°). S.G. 2 760. Prepared from di-propyl ketone by treating with  $PCl_5$  and heating the resulting  $(C_7H_{11})_2CCl_2$  with alcoholic KOH for 20 hours at 140° (Béhal, *Bl.* [2] 48, 216; A. Ch. [6] 15, 413). Liquid, with strong odour resembling acetylene. Does not react with ammoniacal  $Cu_2Cl_2$ . Forms a white compound with  $HgCl_2$ , which when treated with dilute HCl reproduces di-propyl ketone. Combines energetically with bromine. If the hydrocarbon be dissolved in conc.  $H_2SO_4$  and the solution be diluted with ice, di-propyl ketone is obtained.

Heptene  $C_7H_{12}$ , i.e.  $Me_2C:C:Me_2$ . *Tetra-methyl-allylene*. (70°). From di-isopropyl ketone by successive treatment with  $PCl_5$  and alcoholic KOH (Henry, B. 8, 400). Does not ppt. ammoniacal  $AgNO_3$  or  $Cu_2Cl_2$ .

Heptene  $C_7H_{12}$ . *Heptylidene*. (115°–125°). Formed in small quantity in distilling calcium succinate (Funaro, G. 11, 276).

**HEPTINENE GLYCOL** v. Di-oxy-HEPTINENE. **HEPTINOIC ACID**  $C_7H_{12}O_3$ , i.e.  $Pr.CH_2.CiC.CO.H$ . *Butyl-acetylene carboxylic acid*. (135° at 20 mm.). From methyl-propyl-acetylene (hexene) by heating with sodium at 165° and treating the product, suspended in ether, with  $CO_2$  (Favorsky, J. R. 1887, 553). Oil, which does not solidify at -20°. The silver salt soon decomposes into  $CO_2$  and silver hexene.

**Salts.**— $\text{CaA}'_2$ : slender needles (from water).— $\text{BaA}'_2$ : small spangles (after drying over  $\text{H}_2\text{SO}_4$ ).

**HEPTINYL ALCOHOL**  $\text{C}_7\text{H}_{15}\text{O}$  i.e.  $(\text{CH}_2)_6\text{CH}_2\text{OH}$ . *Di-allyl-carbinol*. (151° cor.). S.G.  $\frac{2}{20}$  8758;  $\frac{15}{15}$  8644. Formed by the action of zinc on a mixture of allyl iodide (2 vols.) and formic ether (1 vol.); the mixture is kept cold, and is finally mixed with water and distilled (Saytzeff, A. 185, 129; B. 9, 1600). A by-product in its preparation boils at c. 211°, and appears to be  $\text{C}_{10}\text{H}_{19}\text{O}$ , or di-allyl-carbinol, in which one H is displaced by propyl (V. Schestakoff, J. pr. [2] 30, 215). Di-allyl-carbinol is an oil. It unites with bromine, forming a tetrabromide. Chromic acid mixture oxidises it to formic acid and  $\text{CO}_2$ , no acetic acid being produced.  $\text{KMnO}_4$  gives oxalic acid and an acid  $\text{C}_4\text{H}_8\text{O}_4$  (Schirkoff, J. pr. [2] 23, 207). With  $\text{HClO}_4$ , followed by elimination of Cl, it gives, not  $\text{C}_7\text{H}_{11}(\text{OH})$ , but its anhydride  $\text{C}_7\text{H}_{11}(\text{OH})_2\text{O}$  (S. Reformatsky, J. pr. [2] 31, 318).

**Acetyl derivative**  $\text{C}_7\text{H}_{13}\text{OAc}$ . (170° cor.). S.G.  $\frac{2}{20}$  9167;  $\frac{15}{15}$  8997 (Saytzeff, A. 185, 136).

**Methyl ether**  $(\text{C}_7\text{H}_{13})\text{CH}_2\text{OMe}$ . (136°  $\frac{2}{20}$  V.). S.G.  $\frac{2}{20}$  826;  $\frac{15}{15}$  810. C.E. (0°–20°) 001. Formed by the action of sodium and MeI on the alcohol (K. Rjabinin, J. pr. [2] 23, 270). **Reactions.**—1. When bromine is added to an ethereal solution combination takes place, a tetra-bromide,  $(\text{C}_7\text{H}_{13}\text{Br})_2\text{CH}_2\text{OMe}$ , being formed.—2. Oxidised by  $\text{KMnO}_4$ , the double unions are broken, the product being the methyl derivative of  $\beta$ -oxylutic acid  $(\text{CO}, \text{H}, \text{CH}_2)_2\text{CH}_2\text{OMe}$  (q. v.).

**Ethyl ether**  $(\text{C}_7\text{H}_{13})\text{CH}_2\text{OEt}$ . (144° i. V.). S.G.  $\frac{2}{20}$  821;  $\frac{15}{15}$  803. C.E. (0°–20°) 0012. From the alcohol by sodium and EtI (Rjabinin, J. pr. [2] 23, 272).

**HEPTINYL CHLORIDE**  $\text{C}_7\text{H}_{13}\text{Cl}$  i.e.  $(\text{CH}_2)_6\text{CH}_2\text{CH}_2\text{Cl}$ . (144°). From heptyl alcohol and  $\text{PCl}_5$ . Converted by alcoholic KOH into heptene  $\text{C}_7\text{H}_{12}$  (115°).

**HEPTINYL GLYCOL**  $\text{C}_9\text{H}_{19}\text{O}_2$  Di-oxy-heptylene. **n-HEPTOIC ACID**  $\text{C}_7\text{H}_{13}\text{O}_2$  i.e.  $\text{Pr}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CO}_2\text{H}$ . *Enanthic acid*. Mol. w. 130. [–10.5°]. (223°) (222° cor.) (Perkin, C. J. 45, 484). S.G.  $\frac{2}{20}$  9313 (Zander, A. 224, 69);  $\frac{15}{15}$  9225;  $\frac{25}{25}$  9160;  $\frac{30}{30}$  9160 (Brühl). C.E. (0°–10°) 00037. M.M. 7.552 at 14.5°.  $\mu_D^{20}$  1.4266 (B.).  $n_D^{20}$  58.19. S.V. 174.6 (Z.).

**Formation.**—1. By the oxidation of enanthol with nitric or chromic acid (Bussy, J. Ph. [3] 8, 329; A. 60, 248; Tilley, A. 67, 107; Schneider, A. 70, 112; Schorlemmer, A. Grimshaw, C. J. 26, 1073; A. 170, 141; Mehlis, A. 185, 358).—2. By oxidation of castor oil (Tilley, A. 39, 160; cf. Arzbücher, A. 73, 200; Brazier, A. Grossleth, A. 75, 249).—3. By the action of  $\text{HNO}_3$  on oleic acid (Laurent, A. Redtenbacher, A. 59, 50).—4. By saponification of heptyl cyanide, obtained from n-hexyl alcohol (Lieben, A. Janacek, A. 187, 126).—5. By oxidation of n-heptyl alcohol (Schorlemmer, Pr. 14, 171; A. 161, 279; 170, 141).—6. By reducing isodulcitol carboxylic acid with HI and phosphorus (E. Fischer, B. 21, 2175).—7. By the action of  $\text{HNO}_3$  on Chinese wax (Buckton, C. J. 10, 166), on azelaic acid, and on spermaceti (Arppe, A. 120, 288).—8. By fusing sebacic acid with potash (Koch, A. 119, 178).—9. By boiling the barium salt of mannite

carboxylic acid with aqueous HI and red phosphorus, diluting, and extracting with ether. The ethereal solution is shaken with mercury, and the product treated with  $\text{H}_2\text{SO}_4$  and zinc dust. The acid is finally distilled over with steam (E. Fischer, A. Hirschberger, B. 22, 372).

**Preparation.**—Enanthol (1 pt.) is treated in the cold with dilute  $\text{HNO}_3$  (2 pts. composed of 1 vol.  $\text{HNO}_3$  S.G. 1.4 and 2 vols. water); the resulting acid is distilled *in vacuo* (Krafft, B. 15, 1717).

**Properties.**—Liquid. Gives propionic and succinic acids when oxidised by chromic acid mixture.

**Salts.**—Ammonium salt is v. sol. water, alcohol, and ether, and non-crystalline.— $\text{KA}'$  (at 100°): silky mass.— $\text{NaA}'$ : needles; often obtained as a jelly.— $\text{CaA}'_2$ : thin flat needles. S. 914 at 8.5° (S. a. G.).— $\text{CaA}'_2$ , aq: thin needles. S. (of  $\text{CaA}'_2$ ) 94 at 12° (L. a. J.).— $\text{BaA}'_2$ : thin laminae or broad needles. [239°] (M.). S. 1.76 at 12° (G. a. S.); 1.56 at 22° (M.); 1.68 at 9° (L. a. J.).— $\text{ZnA}'_2$ : prisms (from alcohol); sl. sol. water, v. sol. alcohol. [132°].— $\text{ZnA}'_2$ , aq.— $\text{CdA}'_2$ : laminae. [96°].— $\text{PbA}'_2$ : laminae (from hot water).— $\text{CuA}'_2$ : green prisms (from alcohol).— $\text{AgA}'$ : small woolly needles (from hot water); insol. cold water and alcohol, sl. sol. boiling water.

**Methyl ether**  $\text{MeA}'$ . (180°) (Neuhof, J. 1866, 323); (173°) (Cahours, A. Demarçay, B. [2] 34, 481); (172°) (Gartenmeister, A. 233, 249). S.G.  $\frac{2}{20}$  887 (N.);  $\frac{15}{15}$  889 (S. a. D.);  $\frac{25}{25}$  8981 (G.). S.V. 196.2. C.E. (0°–10°) 00102.

**Ethyl ether**  $\text{EtA}'$ . (188° i. V.). S.G.  $\frac{2}{20}$  8879 (L. a. J.);  $\frac{15}{15}$  8861 (G.);  $\frac{25}{25}$  8718;  $\frac{30}{30}$  8048 (Perkin, C. J. 45, 502). M.M. 9.54 at 14.9°. C.E. (0°–10°) 00101 (G.). By boiling the ether (20 c.c.) with m-amido-benzoic acid (10 g.) for eight hours there is formed  $\text{C}_7\text{H}_{13}\text{O.NH.C}_6\text{H}_4\text{CO}_2\text{H}$  [202°] (Pellizzari, A. 232, 149).

**Propyl ether**  $\text{PrA}'$ . (206.4°). S.G.  $\frac{2}{20}$  8824. C.E. (0°–10°) 0097. S.V. 246.5 (G.).

**Butyl ether**  $\text{PrCH}_2\text{A}'$ . (225.1°). S.G.  $\frac{2}{20}$  8807. C.E. (0°–10°) 00692. S.V. 271.3 (G.).

**n-Heptyl ether**  $\text{C}_7\text{H}_{13}\text{A}'$ . (274.6°) (G.); (277° cor.). S.G.  $\frac{15}{15}$  870 (Cross, C. J. 32, 123; B. 10, 1602);  $\frac{25}{25}$  8652;  $\frac{30}{30}$  8593 (Perkin);  $\frac{35}{35}$  8761. C.E. (0°–10°) 00086. S.V. 350.2. M.M. 14.655 at 13.6°.

**Octyl ether**  $\text{C}_7\text{H}_{13}\text{A}'$ . (290.4°). S.G.  $\frac{2}{20}$  8757. S.V. 376.2. C.E. (0°–10°) 00086 (Gartenmeister).

**Phenyl ether**  $\text{C}_7\text{H}_{13}\text{A}'$ . (275°–280°). From the chloride  $\text{C}_7\text{H}_{13}\text{OCl}$  and phenol (Cahours, C. R. 39, 257).

**Amide**  $\text{C}_7\text{H}_{13}\text{CONH}_2$ . [96°]. (250°–258°). Formed by heating the ammonium salt to 230° (Hofmann, B. 15, 983), and by the action of  $\text{NH}_3$  on the anhydride (Mehlis, A. 185, 368). Laminae (from water) or needles (from alcohol). Converted by a mixture of KOH and bromine into  $\text{C}_7\text{H}_{13}\text{NH.CO.NH.CO.C}_6\text{H}_5$  [97°] (Hofmann, B. 15, 759).

**Methyl-amide**  $\text{C}_7\text{H}_{13}\text{CONHMe}$ . (266°). S.G.  $\frac{15}{15}$  895. Thick liquid. Obtained by heating the acid with methylamine for 5 hours at 230°, dissolving the product in ether, and adding  $\text{K}_2\text{CO}_3$  (Franchimont, A. Klobbe, R. T. O. 6, 247).

**Di-methyl-amide**  $\text{C}_7\text{H}_{13}\text{CONMe}_2$ . (243°). S.G.  $\frac{15}{15}$  894.

**Ethylamide**  $\text{C}_7\text{H}_{13}\text{CONHET}$ . [6°]. (268°).

## HEPTOIC ACID.

Formed by heating the ethyl-ammonium salt at 230°. Decomposed by pure  $\text{HNO}_3$  with evolution of  $\text{N}_2\text{O}$  (Franchimont a. Klobbie, *R. T. O.* 6, 248).

*Di-ethyl-amide*  $\text{C}_2\text{H}_5\text{CO.NEt}_2$ . (258°). S.G. 15-881. Liquid (F. a. K.).

*Anhydride*  $(\text{C}_2\text{H}_5\text{CO})_2\text{O}$ . Mol. w. 242. (268°-271°). S.G. 21-932. Obtained by distilling the acid with  $\text{PCl}_5$ , and heating the resulting heptyl chloride with potassium hepteoate (Mehlis; cf. Chiozza a. Malerba, *A.* 91, 102).

*Nitrile*  $\text{C}_7\text{H}_{13}\text{CN}$ . (175°-178° i. V.). S.G. 22-895. Formed by heating heptoic acid with potassium sulphocyanide (Mehlis). Formed also by the action of  $\text{Ac}_2\text{O}$  on the oxim of heptoic aldehyde (Lach, *B.* 17, 1572); and, together with heptylamine, by allowing a mixture of the amide of octoic acid (1 mol.), and bromine (3 mols.) to run into a 10 p.c. solution of  $\text{NaOH}$  (Hofmann, *B.* 17, 1407). Oil; sol. alcohol and ether.

*Chloride*  $\text{C}_7\text{H}_{13}\text{COCl}$ . With di-methylaniline in presence of  $\text{ZnCl}_2$  it gives as condensation products,  $\text{C}_7\text{H}_{13}\text{CO.C}_6\text{H}_4\text{NMe}_2$ , and a base  $\text{C}_{22}\text{H}_{33}\text{N}_2$ . This latter body has all the properties of a leuco-base. Heated with  $\text{MeI}$  at 100° it gives the salt  $\text{C}_{22}\text{H}_{33}\text{N}_2\text{MeI}$ . Oxidising agents act on it very easily, and develop a fine blue colour;  $\text{FeCl}_3$  gives  $\text{C}_{22}\text{H}_{33}\text{N}_2\text{HCl}$ , having a fine blue colour. This is reduced by  $\text{Zn}$  in acid solution to the original leuco-base. The blue colour disappears with excess of acid.  $\text{KOH}$  or  $\text{NaOH}$  does not set free the base, but causes a complete decomposition (Auger, *Bl.* [2] 47, 48).

*Isoheptoic acid*  $\text{Pr.CH}_2\text{CHMe.CO}_2\text{H}$ . *Methyl-butyl-acetic acid*. *Butyl-propionic acid*. (212°). S.G. 3-9305; 3-9138. S. -36 at 4°. Formed by saponification of the corresponding nitrile which is obtained from  $\text{KC}_7$  and the secondary hexyl iodide derived from mannite (Hecht, *A.* 209, 309; Hecht a. Munier, *B.* 11, 1781). Colourless oil; sl. sol. water, miscible with alcohol, ether and chloroform. On oxidation with chromic acid mixture it yields acetic and butyric acids. A solution of its  $\text{Na}$  salt gives white pps. with salts of  $\text{Ca}$ ,  $\text{Al}$ ,  $\text{Zn}$ ,  $\text{Cd}$ ,  $\text{Mn}$ ,  $\text{Hg}$ ,  $\text{Pb}$ , and  $\text{Ag}$ ; a brown pp. with  $\text{FeCl}_3$ , a green pp. with  $\text{NiCl}_2$ , and a blue pp. with  $\text{CuSO}_4$ .

**Salts.**— $\text{KA}'$ : very deliquescent, and v. e. sol. water.— $\text{NaA}'$ : very deliquescent.— $\text{LiA}'$ : crystalline; v. sol. water, m. sol. alcohol.— $\text{CaA}'_2$  13aq: S. 11.9 at 1°; 13.9 at 6.7°; 12.1 at 16.6°; 11.8 at 28°; 6.1 at 160°.— $\text{SrA}'_2$  2aq: grouped needles. S. 19.2 at 3°.— $\text{BaA}'_2$  13aq: crystalline aggregates. S. (of  $\text{BaA}'_2$ ) 30 at 1°.— $\text{AgA}'$ : S. 23 at 4°.

*Methyl ether*  $\text{MeA}'$ . (157° i. V.). S.G. 15-879.

*Ethyl ether*  $\text{EtA}'$ . (173° i. V.). S.G. 15-8685; 15-8570.

*Propyl ether*  $\text{PrA}'$ . (192° i. V.). S.G. 15-8635.

*Isopropyl ether*  $\text{PrA}'$ . (177°). S.G. 15-859.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$  i.e.  $\text{Pr.CH}_2\text{CHMe.CO}_2\text{H}$ . (210° cor.). Formed from methyl-butyl-aceto-acetic ether and conc. alcoholic  $\text{KOH}$ . Formed from levulose by shaking with  $\text{HCl}$ , decomposing the resulting  $\text{C}_7\text{H}_{13}\text{NO}_4$  by fuming  $\text{HCl}$  aq, and reducing the product

with  $\text{HI}$  and phosphorus (Kiliani, *B.* 18, 3066; 19, 221). Oil.— $\text{CaA}'_2$  6aq: long needles. S. (of  $\text{CaA}'_2$ ) 7.8 at 17.5°.— $\text{SrA}'_2$  5aq. This acid should be identical with the preceding, but does not seem to be so.

*Heptoic acid*

$(\text{CH}_3)_2\text{CH.CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  (?) *Iso-amyl-acetic* or *iso-aminomyllic acid*. (216.5°-218° cor.). S.G. 15-926. Formed when  $\text{CO}$  is passed at 180° over  $\text{NaOAc}$  mixed with  $\text{NaOC}_2\text{H}_5$  (Poetsch, *A.* 218, 67).

**Salts.**— $\text{NaA}'$  aq.— $\text{CaA}'_2$  3aq.

*Methyl ether*  $\text{MeA}'$ . (166°-167.5° cor.). S.G. 15-884.

*Ethyl ether*  $\text{EtA}'$  (182° cor.). S.G. 15-872. Not attacked by alcoholic  $\text{NH}_3$  at 120°.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$ . (210°-213°). Formed from isohexane ( $\text{C}_7\text{H}_{13}\text{O}_2$ )  $\text{Pr.CH}_2\text{Pr}$  by chlorinating, displacing  $\text{Cl}$  by  $\text{OH}$ , and oxidising the resulting heptyl alcohol (Grimshaw, *A.* 166, 163). Oil, with unpleasant odour. Probably identical with isohexanoic acid.— $\text{CaA}'_2$  2aq: small needles.— $\text{AgA}'$ : small needles. The barium salt is amorphous.

*Heptoic acid*  $(\text{CH}_3)_2\text{CH.CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ .

*Isoamyl-acetic acid*. An oil, formed by treating acetic ether with sodium and isomyl iodide successively, the resulting isomyl-aceto-acetic ether being saponified (Frankland a. Duppa, *A.* 138, 338). Probably identical with the acid of Poetsch.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$ . (209°-213°). Formed by oxidising the isohexane (90°) in Pennsylvanian petroleum (Schorlemmer, *C. J.* 26, 319). Its barium salt is amorphous. The calcium salt crystallises by spontaneous evaporation in long transparent needles or prisms. The silver salt is a flocculent pp.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$  i.e.  $\text{CH}_3\text{CET}_2\text{CO}_2\text{H}$ .

*Di-ethyl-propionic acid*. (208°). Formed by acting on  $\text{ZnEt}_2$  with acetyl chloride; converting the resulting  $\text{CMeEt}_2\text{Cl}$  into the corresponding iodide; heating this compound with  $\text{KC}_7$  for a week; and digesting the resulting  $\text{CMeEt}_2\text{Cy}$  with fuming  $\text{HCl}$  aq (Idanoff, *Bl.* [2] 26, 450). Oil.— $\text{BaA}'_2$  5aq: separates on rapid cooling in stellate groups of flat needles; on slow cooling in flat prisms.— $\text{KA}'$ : very soluble, and non-crystalline.— $\text{KHA}'_2$ : stellate groups of needles.—The silver salt is sl. sol. boiling water, separating as tufts of small needles.—The lead salt is a white pp. sl. sol. cold water, the solution becoming turbid when heated.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$  i.e.

$(\text{CH}_3)_2\text{CH.CHMe.CH}_2\text{CO}_2\text{H}$  (?). (220°). Formed by passing  $\text{CO}$  over a mixture of  $\text{NaOEt}$  and sodium isovalerate at 160° (Looss, *A.* 202, 321). Oil.

*Heptoic acid*  $\text{C}_7\text{H}_{13}\text{O}_2$ . *Amelienic acid*.

(185°-230°). Obtained, together with  $\text{CO}_2$  and acetic acid, by oxidising diamylene with  $\text{K}_2\text{CrO}_4$  and dilute  $\text{H}_2\text{SO}_4$  (Von Schneider, *A.* 157, 185). Oil, lighter than water. Its salts are decomposed even by  $\text{CO}_2$ . The  $\text{K}$ ,  $\text{NH}_4$ ,  $\text{Ca}$ , and  $\text{Mg}$  salts are crystallisable and v. sol. water.— $\text{SrA}'_2$  8aq: small needles (Wyschnegradsky a. Pawloff, *J. R.* 7, 170).— $\text{ZnA}'_2$ : nodules, sl. sol. cold water; the aqueous solution deposits a gelatinous pp. when heated.— $\text{AgA}'$ : pulverulent pp., sl. sol. water.

**Heptoic acid**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . *Ethyl-propyl-acetic acid*. (209° cor.). From ethyl-propyl-aceto-acetic ether by saponification with conc. alcoholic KOH (Kiliani, B. 19, 227).  $\text{OM.} - \text{CaA}'_2, 2\text{aq.}$ : soft needles. S. (of  $\text{CaA}'_2$ ) 11.4 at 19.5°.  $-\text{SrA}'_2, 2\text{aq.}$ : small prisms. S. (of  $\text{SrA}'_2$ ) 27.9.  $-\text{PbA}'_2, 3\text{aq.} - \text{CuA}'_2$ : The silver, barium, and lead salts form colourless needles. The acid is perhaps identical with that of Hecht.

*References.*—AMIDO-, and BROMO-, HEPTOIC ACIDS.

#### HEPTOIC ALDEHYDE $\text{C}_7\text{H}_{14}\text{O}$ i.e.

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHO}$ . *Enanthol*. Mol. w. 114. (165°). S.G. 20° 8495 (Brühl);  $d_4^{20}$  8226;  $d_4^{25}$  8158 (Perkin, C. J. 45, 477). V.D. 4.14 (calc. 3.95).  $\mu_s$  1.4309.  $R_D$  55.59. M.M. 7.422 at 16.2°. The name enanthol is due to the belief of Liebig that heptoic acid was the chief product of the saponification of fustil oil from wine (Liebig, A. Pelouze, A. 19, 241). Obtained by distilling castor oil (Bussey, A. 60, 246; J. Ph. 13, 62; [8] 8, 821; H. Schiff, Z. 1870, 77; Krafft, B. 10, 2035). Purified by preparing its compound with  $\text{NaHSO}_4$  which are subsequently distilled with  $\text{Na}_2\text{CO}_3$  (Bartagnini, A. 85, 281). Dried over  $\text{Na}_2\text{SO}_4$  and rectified (Erlenmeyer, A. Sigel, A. 176, 342). The yield is 12 p.c. of the castor oil (Jourdan, A. 200, 102). Oil, miscible with alcohol and ether. Has a strong odour. When moist heptoic aldehyde is exposed for a long time to a low temperature it deposits crystals of a hydrate  $\text{C}_7\text{H}_{14}\text{O} \cdot 2\text{aq}$  (? heptoic orthoaldehyde) (Bouis, A. Ch. 44, 87). Heptoic aldehyde reduces  $\text{AgNO}_3$ , forming a mirror.

*Reactions.*—1. Heptoic aldehyde is polymerised by prolonged contact with  $\text{K}_2\text{CO}_3$ . The product is a crystalline solid [53°] which, when heated, begins to decompose at 115° into heptoic aldehyde, the aldehyde  $\text{C}_9\text{H}_{18}\text{CHO}$ , and an aldehyde  $\text{C}_{11}\text{H}_{22}\text{O}$  (c. 335° at 250 mm.). The solid polymeride when treated in acetic acid solution with sodium yields heptyl alcohol and a substance  $\text{C}_{11}\text{H}_{22}\text{O}_2$  (Braylants, B. 8, 414; Perkin, jun., C. J. 43, 87).—2. Alcoholate (1.5 p.c.) potash yields tetradecenoic (amyl-hexyl-acrylic) acid  $\text{C}_{14}\text{H}_{28}\text{O}_2$ , its aldehyde  $\text{C}_{14}\text{H}_{26}\text{O}$ , the aldehyde  $\text{C}_{12}\text{H}_{24}\text{O}$ , and heptoic acid (Perkin, jun., C. J. 43, 67; B. 15, 2806).—3. Conc. KOHAq also forms condensation products, together with heptoic acid. 4. Solid KOH polymerises heptoic aldehyde even at 0°, forming a solid and a liquid polymeride. Each of these bodies when distilled gives heptoic aldehyde, tetradecenoic aldehyde, and  $\text{C}_{12}\text{H}_{24}\text{O}$  (Borodin, B. 5, 481; 6, 982). Solid KOH at 120° forms an oil  $\text{C}_{14}\text{H}_{28}\text{O}$  which boils with decomposition, at 260° (Tilley, P. M. 33, 81; A. 67, 109).—5.  $\text{ZnCl}_2$  forms the aldehyde  $\text{C}_{11}\text{H}_{22}\text{O}$ . 6. Cold conc.  $\text{HNO}_3$  forms a solid isomeride 'metenanthol'.—7. Dilute chromic acid mixture forms heptoic acid.—8. When left for some weeks in contact with quicklime, there is formed heptyl alcohol, heptoic acid, heptylene (95°–100°), octylene (122°–125°), ennylene (145°), and the ketone  $\text{C}_{11}\text{H}_{22}\text{O}$  (Fittig, A. 117, 76).—9. In acetic acid solution sodium reduces it, forming heptyl alcohol, tetradecenyl alcohol  $\text{C}_{14}\text{H}_{28}\text{CH}_2\text{OH}$ , and tetradecenoic aldehyde  $\text{C}_{14}\text{H}_{26}\text{CHO}$  (Perkin). In a wet ethereal solution Na forms heptyl alcohol, heptoic acid, tetradecenoic aldehyde, and a body  $\text{C}_{11}\text{H}_{20}\text{O}$ .—10.  $\text{PCl}_5$  forms di-chloro-heptane  $\text{C}_7\text{H}_{14}\text{CHCl}_2$ .—11.  $\text{PCl}_5\text{Br}_2$  forms  $\text{C}_7\text{H}_{13}\text{CHBr}_2$ .

*Chlorine* forms oily  $\text{C}_7\text{H}_{13}\text{Cl}_2\text{O}$  (A. W. Williamson, A. 61, 44).—12. *Resorcin* and dilute HCl form a resin in the cold (Michael & Ryder, Am. 9, 134). 13. Heptoic aldehyde (20 g.) heated with trimethylene glycol (30 g.) at 160° gives rise to  $\text{C}_7\text{H}_{13}\text{CH} \begin{smallmatrix} \text{O} \cdot \text{CH}_2 \\ \text{O} \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$ , an oil, (c. 216°), S.G. 2.933. With glycol, in like manner, it forms  $\text{C}_7\text{H}_{13}\text{CH} \begin{smallmatrix} \text{O} \cdot \text{CH}_2 \\ \text{O} \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$  (Lochert, A. Ch. [6] 16, 35, 52).—14.  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  at 170° give enneoic acid (Schneegans, A. 227, 85).—15.  $\text{Ac}_2\text{O}$  and barium succinate give hexyl-paraconic acid (Schneegans).—16. *Aqueous ammonia* (150 g. of S.G. 89) added to cooled heptoic aldehyde (80 g.) forms an oily layer of heptoic aldehyde ammonia  $\text{C}_7\text{H}_{13}\text{CH}(\text{OH})\text{NH}_2$  (Erlenmeyer & Sigel, A. 176, 343).—17. *Dry ammonia* passed into dry heptoic aldehyde forms heptoic hydramide  $\text{C}_7\text{H}_{13}\text{CH}_2\text{N}$ , which boils above 400° and does not combine with acids. The hydramide is converted by boiling water into a yellow oil  $\text{C}_7\text{H}_{13}\text{NO}$ , and by water at 125° into  $\text{C}_7\text{H}_{13}\text{NO}_2$ , which is also a yellow neutral oil (Schiff, A. Suppl. 3, 367; Suppl. 6, 24).—18. Colourless ammonium sulphide in concentrated solution forms heptoic thialdine  $\text{C}_{11}\text{H}_{21}\text{NS}$ , a colourless oil, S.G. 21.836. It forms a hydrochloride  $\text{B} \cdot \text{HCl}$ , which is insol. water, and crystallises from alcohol in needles (Schiff).—19. A solution of heptoic aldehyde saturated with ammonia is converted by hydrogen cyanide into oily  $\text{C}_7\text{H}_{13}\text{CH}(\text{NH}_2)\text{CN}$ , and another oil  $\text{C}_{11}\text{H}_{21}\text{N}$  (Erlenmeyer & Sigel, A. 177, 111).—20. If heptoic aldehyde (100 pts.) be mixed with a little  $\text{PCl}_5$  (1 pt.) and dry hydrogen sulphide be passed in, there is formed the compound  $\text{C}_7\text{H}_{13}\text{CH} \begin{smallmatrix} \text{O} \\ \text{S} \end{smallmatrix} \text{CH} \cdot \text{C}_7\text{H}_{13}$ , (200°–250°).

S.G. 22.875 (Schiff).—21. An alcoholic solution of heptoic aldehyde, on saturation with HCl, yields  $\text{C}_7\text{H}_{13}\text{CHCl}(\text{OEt})$ , a light oil, which is decomposed on distillation into a mixture of hydrocarbons and other bodies (Williamson; Schiff, Z. [2] 6, 74).—22. *Phosphonium iodide* at 0° forms  $\text{C}_7\text{H}_{13}\text{CH}(\text{OH})\text{PI}$ , which crystallises in minute leaflets, [122°], insol. water, sl. sol. ether, v. sol. alcohol (Girard, A. Ch. [6] 2, 40).—23. *Isoamylamine* forms  $\text{C}_7\text{H}_{13}\text{CH} \cdot \text{NC}_5\text{H}_{11}$ , a yellow, non-volatile, basic oil (Schiff, Z. 140, 93).—24. Heptoic aldehyde (70 g.) heated with aniline (57 g.) and HOAc (150 g.) at 100° forms  $\text{C}_7\text{H}_{13}\text{CH}(\text{OH})\text{NHPH}$ , a red oil with pleasant odour (Leeds, A. C. J. 5, 2).—25. By heating with aniline or di-phenylurea there is formed  $\text{C}_7\text{H}_{13}\text{CH} \cdot \text{NPH}$  (or  $\text{C}_7\text{H}_{13}\text{CH}(\text{NPH})$ ), a neutral yellow oil, which combines with isoamyl iodide at 100° forming  $\text{C}_7\text{H}_{13}\text{N} \cdot \text{C}_5\text{H}_{11}\text{I}$  (Schiff, A. 148, 336; Suppl. 3, 351).—26. *Benzoyl-aniline* forms  $\text{C}_7\text{H}_{13}\text{CH}(\text{NPhBz})$ , which is split up on distillation into  $\text{Bz}_2\text{O}$  and  $\text{C}_7\text{H}_{13}\text{CH}_2(\text{NPh})$  (Schiff).—27. *Ethyl-aniline* forms  $\text{C}_7\text{H}_{13}\text{CH} \cdot \text{NHEt}$ , (215°–220°), a neutral oil.—28. *Allyl-aniline* forms  $\text{C}_7\text{H}_{13}\text{CH}(\text{NPhC}_3\text{H}_5)$ , a neutral oil.—29. *Di-phenyl-thio-urea* in the cold forms  $\text{C}_7\text{H}_{13}\text{CH} \begin{smallmatrix} \text{NPH} \\ \text{NPH} \end{smallmatrix} \text{CS}$ , a neutral solid, sol. ether (Schiff).—30. *Xylidine* in glacial acetic acid forms, according to Leeds (A. C. J. 5, 2), a red liquid  $\text{C}_7\text{H}_{13}\text{CH}(\text{OH})\text{NHC}_6\text{H}_4\text{Me}$ , with pleasant odour. 31. (a) *Naphthylamine* in HOAc forms in like manner  $\text{C}_7\text{H}_{13}\text{CH}(\text{OH})\text{NHC}_{10}\text{H}_7$ , a red liquid.

smelling like pine-apples (Leeds).—82. (a) *Naphthylamine* added to a dry ethereal solution of heptioic aldehyde forms a yellow, amorphous, neutral substance  $(C_6H_5)_2CH(NC_6H_5)_2$ ; insol. water, sol. alcohol and ether (Papasogli, A. 171, 189).—83. Treated with *di-methyl-aniline* in presence of  $ZnCl_2$ , there is formed (together with products resulting from the polymerisation of the aldehyde) a condensation product  $C_{22}H_{17}N_2$  or  $C_6H_5CH(C_6H_5NMe_2)_2$ . This forms long colourless needles  $[59.5^\circ]$ ,  $(275^\circ \text{ at } 15 \text{ mm.})$ ; sl. sol. cold alcohol, insol. water. On oxidation this base does not yield the corresponding carbinol, but gives a passing colouration and an odour of *œnanthol* (Auger, *Bl.* [2] 47, 42).—84.  $ZnEt_2$ , followed by water forms the alcohol  $C_6H_5CH(OH)SO_2NH_2$  (Wagner, *B.* 17, Ref. 315, Ref.).—85. Heptioic aldehyde (75 g.) heated with *aniline* (20 g.) and conc.  $HClAq$  (60 g.) for 2 hours at  $100^\circ$  forms *amyl-hexyl-quinoline* (Dæbner a. Miller, *B.* 17, 1719).

**Combinations with sulphites.**—The combinations with bisulphites of the alkalis may be obtained directly, or by passing  $SO_2$  into an alcoholic solution of heptioic aldehyde containing potash, soda, or  $NH_3$ .— $C_6H_5CH(OH)SO_2Na$  aq: brilliant unctuous scales; v. sol. water, v. e. sol. hot, nearly insol. cold, alcohol. Decomposed by acids and alkalis, with liberation of heptioic aldehyde. With  $BaCl_2$  its solution gives a pp. of  $(C_6H_5SO_2)_2Ba$ , whence  $H_2SO_4$  liberates oily  $C_6H_5SO_3H$ , a compound which is also formed by passing  $SO_2$  into an aqueous solution of heptioic aldehyde (Mendelejeff, A. 110, 241).— $C_6H_5SO_2NH_2$ : small shining prisms, sl. sol. water and alcohol. Decomposed by boiling water into heptioic aldehyde and acid ammonium sulphite. When heated with potash-lime at  $265^\circ$  it yields tri-hexyl-amine (Petersen a. Gössmann, C. C. 1857, 193).— $(C_6H_5O)_2SO_2(NH_2Ph)_2$ : needles. Obtained by mixing heptioic aldehyde with an ethereal solution of aniline sulphite (Schiff, A. 140, 129).— $C_6H_5SO_2NH_2Ph$ : usually obtained in attempting to prepare the preceding (Schiff, A. 210, 127). Decomposed by water at  $65^\circ$  into  $C_6H_5CH_2NPh$  and crystalline

$C_6H_5CH(OH)SO_2NH_2Ph$  aq.— $C_6H_5CH(OH)SO_2NH_2CH_2CO_2H$ : crystalline mass, insol. ether, sl. sol. alcohol. Obtained by dissolving heptioic aldehyde in an aqueous solution of glyccoll saturated with  $SO_2$  (Schiff, A. 210, 125).

**Phenyl-hydrazide**  $C_6H_5N.NH(C_6H_5)$ .  $(240^\circ \text{ at } 77 \text{ mm.})$ . Oil. Formed by the action of phenyl-hydrazine on *œnanthol* (Reisenegger, B. 16, 668).

**Oxim**  $C_6H_5NOH$ .  $[50^\circ]$ .  $(195^\circ \text{ cor.})$ . Formed by the action of hydroxylamine (base) on *œnanthol* (Westenberger, B. 16, 2992). Large white scales. Sol. alcohol, ether, and hot water. With  $FeCl_3$  it gives a rose-red colouration.  $HCl$  resolves it into its constituents. By the action of  $Ac_2O$  it is converted into the nitrile of heptioic acid (Lach, B. 17, 1572).

**Ethyl ether**  $C_6H_5NOEt$ .  $(186^\circ)$ . Oil.

**HEPTOLACTONE** v. *Lactone of Oxy-heptioic acid*.

**HEPTONENE**  $C_6H_{10}$  i.e.  $CH_2CHCH_2CHCH_2CHCH_2$ . *Heptone*.  $(115^\circ)$ . From di-allyl-carbinyl chloride and alcoholic

$KOH$  (Saytzeff, A. 185, 144). Bromine forms liquid  $C_6H_8Br_2$ .

**Heptonene**  $C_6H_{11}C_2OH$ .  $(c. 112^\circ)$ . S.G.  $^{20}$  7468.  $\mu_D^{20}$  1.4207. From heptioic aldehyde and  $PCl_5$  followed by alcoholic  $KOH$  (Brühl, A. 235, 10).

**Isomeride**: **TOLUENE DIHYDRIDE**.

**HEPTONITRILE** v. *Nitrile of Heptioic acid*.

**HEPTOYL**. The radicle  $C_6H_{13}CO$ .

**HEPTOYL-ACETIC ALDEHYDE**. Sodium derivative  $C_6H_{13}CO.CHNa.CHO$ . Obtained by treating methyl hexyl ketone (1 mol.) and formic ether (1 mol.) with  $NaOEt$  suspended in ether (Meyerwitz, B. 21, 1144). Phenyl-hydrazine converts it into phenyl-hexyl-pyrazole  $C_6H_{13}N_2$ , a thick oil  $(319^\circ)$ .

**HEPTYL**. The radicle  $C_6H_{13}$ .

**Diheptyl** v. **TETRADECANE**.

**HEPTYL ACETATE** v. **HEPTYL ALCOHOL**.

**HEPTYL-ACETIC ACID** v. **ENNOIC ACID**.

**Di-heptyl-acetic acid** v. **HEXADENOIC ACID**.

**HEPTYL-ACETO-ACETIC ETHER** v. **ACETO-ACETIC ACID**.

**HEPTYL-ACETONE** v. **METHYLOCTYLKETONE**.

**HEPTYL ALCOHOL**  $C_6H_{13}O$  i.e.

$CH_3CH_2CH_2CH_2CH_2CH_2CH_2OH$ . Mol. w. 116.  $(175.8^\circ \text{ i.v.})$  (Zander, A. 224, 84);  $(176.5^\circ \text{ i.v.})$  (Grimshaw a. Schorlemmer, C. J. 26, 1081);  $(175.5^\circ)$  (C. F. Cross, C. J. 32, 123);  $(176^\circ \text{ cor.})$  (Perkin). S.G.  $^{20}$  8342 (Z.); 8338 (C.); 8308 (Z.); 8252 (P.). M. M. 7-850 at  $12.6^\circ$ . C.E.  $(0^\circ-10^\circ)$  00083 (Z.). S.V. 168.3 (Z.). Occurs to a small extent (1.5 g.) in brandy (100 litres) (Ordonnan, C. R. 102, 219; cf. Faget, *Bl.* 1862, 59).

**Formation**.—1. By reducing heptioic aldehyde (*œnanthol*) in acetic acid solution with sodium-amalgam; the resulting heptyl acetate being saponified with potash (Schorlemmer, A. 177, 304; cf. Bouissac, Carlet, A. 124, 352; Jourdan, A. 200, 102; Sorabji, C. J. 47, 41).—2. By reducing heptioic aldehyde with zinc-dust and  $HOAc$  (Krafft, B. 16, 1723).—3. From *n*-heptyl chloride (Schorlemmer a. Thorpe, Z. 174, 270). 4. Among the products of the distillation of sodium ricinoleate with  $NaOH$  (Chapman, Z. 1865, 737; Wills, C. J. 6, 307; Petersen, A. 118, 69; Raitton, C. J. 6, 205).

**Properties**.—Liquid; gives *n*-heptioic acid on oxidation.

**Acetyl derivative**  $C_6H_{13}OAc$ .  $(191.5^\circ \text{ cor.})$  (Cross);  $(191.3^\circ \text{ cor.})$  (Gartenmeister). S.G.  $^{20}$  874 (C.); 8891 (G.). S.V. 221.0. C.E.  $(0^\circ-10^\circ)$  00096. When obtained by heating heptioic aldehyde (*œnanthol*) with zinc and glacial  $HOAc$  it boils at  $180^\circ$  according to Bouissac, Carlet (C. R. 55, 140). The rate of formation of this ether has been studied by Menschutkin (Z. P. C. 1, 611).

**Methyl derivative**  $C_6H_{13}OMe$ . **Methyl heptyl oxide**.  $(161^\circ)$  (W.);  $(150^\circ)$  (D.). S.G.  $^{20}$  830 (W.); 7953 (D.). C.E.  $(0^\circ-10^\circ)$  001 (Dobriner, A. 243, 3). From  $NaOC_6H_{13}$  and  $MeI$  (Wills, C. J. 6, 307).

**Ethyl derivative**  $C_6H_{13}OEt$ . **Ethyl heptyl oxide**.  $(166^\circ)$ . S.G.  $^{20}$  790. From *n*-heptyl iodide and  $NaOEt$  (Cross). Wills obtained from  $NaOC_6H_{13}$  and  $EtI$  a compound  $(177^\circ)$ ; S.G.  $^{20}$  791.

***n*-Iso-heptyl alcohol**  $CH_3(CH_2)_4CHMe.CH_2OH$  or  $(CH_3)_2CH(CH_2)_4CH_2OH$ .  $(165^\circ)$  (G.);  $(164^\circ)$  (S.). S.G.  $^{20}$  829 (S.). Obtained, together with

methyl - iso - amyl - carbinol, by passing dry chlorine into the vapour of boiling isoheptane  $(\text{CH}_3)_2\text{CH}(\text{CH}_2)_3\text{CH}_3$ , converting the resulting mixture of chlorides into acetates, and saponifying these (Grimshaw, A. 166, 167; Schorlemmer, *Pr.* 14, 164, 464). It gives a heptioic acid (210°-213°) on oxidation.

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (179°). S.G.  $\frac{16.5}{17.5}$  - 871.

Heptyl alcohol  $\text{C}_7\text{H}_{15}\text{OH}$ . (165°-170°). Obtained by chlorination, &c., from the heptane (90°) which occurs along with *n*-heptane in Pennsylvanian petroleum (Schorlemmer, C. J. 26, 319). Perhaps identical with the preceding alcohol. Gives on oxidation a heptioic acid (209°-213°).

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (180°).

*Sec-heptyl alcohol*  $\text{CH}_3(\text{CH}_2)_4\text{CH}(\text{OH})\text{CH}_3$ .

*Methyl-amyl-carbinol*. (161°) (Schorlemmer, C. J. 26, 319; A. 161, 279); (167°) (Schorlemmer & Thorpe, T. 174, 270). Formed from the *sec*-heptyl chloride which is obtained by chlorinating *n*-heptane. Formed also from petroleum heptylene by treatment with cold conc.  $\text{HClAq}$  and heating with  $\text{HIAq}$  at 120° the portion which does not combine with  $\text{HCl}$ ; the resulting iodide is then heated with  $\text{Pb}(\text{OAc})_2$  and the acetate saponified (Morgan). On oxidation it gives a ketone (151°), and finally acetic and *n*-valeric acid.

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (170°). (Schorlemmer, A. 188, 254).

*Sec-heptyl alcohol*  $\text{Pr}.\text{CH}_2.\text{CH}_2.\text{CH}(\text{OH})\text{CH}_3$ .

*Methyl-isoamyl-carbinol*. (147°); (148°-154°) (P.). S.G.  $\frac{17.3}{17.5}$  - 8185. One of the alcohols obtained from isoheptane  $\text{Pr}.\text{CH}_2.\text{Pr}$  by chlorination &c. (Grimshaw, C. J. 26, 309). Obtained also by reducing methyl isoamyl ketone with sodium amalgam, the yield being 72 p.c. (Rohn, A. 190, 309; Purdie, C. J. 39, 467). Gives on oxidation methyl isoamyl ketone (143°) and finally acetic and isovaleric acids.

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (167°). S.G.  $\frac{17.3}{17.5}$  - 8525.

*Sec-heptyl alcohol*  $\text{C}_7\text{H}_{15}\text{OH}$  *i.e.*

$\text{Et}.\text{CH}(\text{OH})\text{CH}_2.\text{Pr}$ . *Ethyl-butyl-carbinol*. (141°). Formed from petroleum heptane by successive conversion into heptyl chloride, heptylene, heptyl chloride, and heptyl acetate (Morgan, C. J. 23, 801). On oxidation it gives a ketone (141°), and finally acetic and *n*-butyric acids.

*Sec-heptyl alcohol*  $\text{C}_7\text{H}_{15}\text{OH}$ . (149°). Formed together with a primary alcohol (165°-170°) from one of the heptanes (90°) in Pennsylvanian petroleum, by chlorination, &c. (Schorlemmer, C. J. 26, 319). Gives on oxidation a ketone (142°-146°), and finally nothing but acetic acid.

*Sec-heptyl alcohol*  $\text{Pr}.\text{CH}_2.\text{OH}$ . *Di-propyl-carbinol*. (150°) (K.); (154°) (S.); (155°) (U. a. S.). S.G.  $\frac{17.3}{17.5}$  - 8188;  $\frac{17.3}{17.5}$  - 8106 (U. a. S.);  $\frac{17.3}{17.5}$  - 814 (K.);  $\frac{17.3}{17.5}$  - 833. Formed by the action of sodium on di-propyl-ketone mixed with a little water (Friedel, A. Ch. [4] 16, 310; Kurz, A. 161, 205), or by treating *n*-butyryl chloride with zinc propyl followed by water (Stoebhakoff, Bl. [2] 34, 347; 37, 344). Formed also from di-propyl ketone (1 mol.), propyl iodide (3 mols.) and zinc (Ustinoff & Saytzeff, J. pr. [2] 34, 468). Oxidation produces di-propyl-ketone, and finally propionic and butyric acid.

*Acetyl derivative* (170°-172°). S.G.  $\frac{17.3}{17.5}$  - 8587. Volatile liquid, with camphor-like odour, sl. sol. water, miscible with alcohol.

*Sec-heptyl alcohol*  $\text{Pr}.\text{CH}_2.\text{OH}$ . *Di-isopropyl-carbinol*. (131°). S.G.  $\frac{17.3}{17.5}$  - 8323. Formed by reducing di-isopropyl-ketone by sodium-amalgam (Münch, B. 7, 1370; A. 180, 333). Liquid, smelling like peppermint, sl. sol. water, v. sol. alcohol and ether. Chromic acid mixture oxidises it to di-isopropyl-ketone.

*Sec-heptyl alcohol*  $\text{Pr}.\text{CH}_2.\text{C}(\text{Et})_2.\text{OH}$ . *Ethyl-isobutyl-carbinol*. (148°). S.G.  $\frac{17.3}{17.5}$  - 827. Formed by treating isovaleric aldehyde with  $\text{ZnEt}_2$  and water successively (Wagner, Bl. [2] 42, 330). On oxidation it gives ethyl isobutyl ketone, and, finally, acetic and isovaleric acids.

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (163°).

*Tert-heptyl alcohol*  $\text{C}(\text{Et})_2.\text{OH}$ . *Tri-ethyl-carbinol*. (141°-143° i.v.). V.D. 3.74 (for 4.01). S.G.  $\frac{17.3}{17.5}$  - 8389;  $\frac{17.3}{17.5}$  - 8299 (B. a. S.);  $\frac{17.3}{17.5}$  - 859 (N.).

*Formation*.—1. From di-ethyl ketone (1 mol.),  $\text{EtI}$  (3 mols.) and zinc (Barataeff & Saytzeff, J. pr. [2] 34, 463).—2. From  $\text{ZnEt}_2$  and propionyl chloride (Nahapetian, Z. [2] 7, 274; A. 162, 44).

Gives on oxidation  $\text{CO}_2$ , di-ethyl ketone, heptylene, propionic acid, and acetic acid.

*Acetyl derivative*  $\text{C}_7\text{H}_{13}\text{OAc}$ . (160°-163°).

*Tert-heptyl alcohol*  $\text{Pr}.\text{CH}_2.\text{CMe}_2.\text{OH}$ . *Dimethyl-isobutyl-carbinol*. (130°). From pseudo-heptylene  $\text{Me}_2\text{C}:\text{CH}.\text{Pr}$  by passing gaseous  $\text{HI}$  into the hydrocarbon, and decomposing the resulting iodide with moist  $\text{Ag}_2\text{O}$  (Markownikoff, Z. 1871, 268). Formed also by dropping isovaleryl chloride (1 mol.) into cooled zinc methyl (2 mols.), leaving the mixture to itself for a month, and then decomposing it with water (Pawloff, A. 173, 192). Colourless liquid, lighter than water and nearly insoluble therein. Smells like camphor. Gives acetic and isobutyric acids on oxidation.

*Tert-heptyl alcohol*  $\text{CMe}_2.\text{CMe}_2.\text{OH}$ . *Dimethyl-tert-butyl alcohol*. *Penta-methyl-ethyl alcohol*. (17°). (131°). Formed by the action of  $\text{ZnMe}_2$  on  $\text{CMe}_2.\text{CO}.\text{Cl}$ , the product being decomposed by water (Butlerov, A. 177, 176). Formed also from  $\alpha$ -bromo-isobutyryl bromide by treatment with  $\text{ZnMe}_2$  followed by water (Kaschirski, C. C. 1881, 278); and from  $\text{CCl}_3.\text{COCl}$  (1 mol.) and  $\text{ZnMe}_2$  (5 mols.) (Bogomoletz, A. 209, 78). The oily liquid obtained by any of these processes is distilled with steam, and a hydrate  $\text{C}_7\text{H}_{15}\text{O}.\text{aq}$  is got which crystallises in long prisms, sl. sol. water, v. sol. alcohol and ether; it has a burning taste and an odour like camphor. This hydrate melts at 83° and begins to boil at 100°, giving off water, and at 130° the anhydrous alcohol passes over. The dehydration may also be effected by leaving the hydrate in a closed vessel over  $\text{CaCl}_2$  at 100°. The anhydrous alcohol is hygroscopic, readily changing to glistening leaflets of the hydrate.

*Tert-heptyl alcohol*  $\text{C}_7\text{H}_{15}\text{OH}$  *i.e.*

$\text{CHMeEt}.\text{CMe}_2.\text{OH}$ . (189°). S.G.  $\frac{17.3}{17.5}$  - 8487;  $\frac{17.3}{17.5}$  - 8329. Formed by treating  $\alpha$ -bromo-*n*-butyric bromide with  $\text{ZnMe}_2$  followed by water (Kaschirski, C. C. 1881, 278). Oil, smelling like camphor. Gives methyl ethyl ketone, acetone, and  $\text{HOAc}$  on oxidation. Gives rise to a heptylene (92°-95°).

**Tert-heptyl alcohol**  $\text{MeEtPrC.OH}$ . *Methyl-ethyl-propyl carbinol*. (135°–138°) (P.); (140°) (S.). S.G. 22° 828;  $d_4^{20}$  811. From butyryl chloride,  $\text{ZnMe}_2$ , and  $\text{ZnEt}_2$ , followed by water (Pawloff, A. 188, 122). Formed also by treating ethyl propyl ketone with  $\text{MeI}$  and zinc (Sokoloff, J. R. 1887, 587). Gives rise to a heptylene (75°–80°). Chromic acid oxidises it to acetic and propionic acids,  $\text{CO}_2$ , and some ethyl-propyl ketone, together with a small quantity of a heptylene  $\text{C}_7\text{H}_{14}$  (97.4°), S.G. 22° 718;  $d_4^{20}$  709.

**Acetyl derivative**  $\text{CMeEtPrOAc}$ . (159°).

**Tert-heptyl alcohol**  $\text{CMeEtPrC.OH}$ . (124°–127°). From isobutyryl chloride,  $\text{ZnMe}_2$ , and  $\text{ZnEt}_2$  (P.). Gives rise to a heptylene (75°–80°).

**References.**—TETRA-BROMO-HEPTYL ALCOHOL and CHLORO-HEPTYL ALCOHOL.

**n-HEPTYL-AMINE**  $\text{C}_7\text{H}_{15}\text{N}$ . (154°) (H.); (156°) (H. A. D.).

**Preparation.**—1. A mixture of equal mols. of octoic amide and bromine is run into an excess of a 5 p.c. solution of  $\text{KOH}$  at 60°; the yield is 30 p.c. (Hofmann, B. 15, 772; Hoogewerff A. Van Dorp, R. T. C. 6, 386).—2. An alcoholic solution of *n*-heptioic aldehyde-phenylhydrazide is reduced by means of sodium-amalgam and acetic acid at 25°–30°; the yield is 23 p.c. of the theoretical (Tafel, B. 19, 1928).

**Properties.**—Liquid; forms a carbonate on exposure to the air.— $\text{B}^*\text{H}_2\text{PtCl}_2$ ; blackens between 220°–230°.—Picrate  $\text{B}^*\text{C}_7\text{H}_{15}\text{N}_2\text{O}_6$ ; needles [121°].

**Heptylamine**  $\text{C}_7\text{H}_{15}\text{NH}_2$ . (146°). Formed by heating heptyl chloride (from petroleum heptane) with ammonia at 120° for several days; di- and tri-heptylamines being also produced (Schorlemmer, C. J. 16, 221; cf. Cahours a. Pelouze, A. Ch. [4] 1, 5). Light oil, smelling like ammonia, m. sol. water, but separated from its aqueous solution by  $\text{KOH}$ .—The hydrochloride crystallises in small scales, v. sol. cold water.— $\text{B}^*\text{H}_2\text{PtCl}_2$ ; small yellow scales, sl. sol. cold, v. sol. hot, water; sol. alcohol and ether.

**HEPTYL-BENZENE**  $\text{C}_{13}\text{H}_{20}$  i.e.  $\text{C}_6\text{H}_{11}\cdot\text{C}_7\text{H}_{13}$ . (110° at 15 mm.). Formed, together with  $\text{C}_8\text{H}_{16}(\text{C}_6\text{H}_5)_2$ , by the action of  $\text{AlCl}_3$  on a mixture of  $\text{C}_6\text{H}_{13}\text{CHCl}_2$  and benzene (Auger, Bl. [2] 47, 50; Kraft, B. 19, 2982). When nitrated at 10° it gives  $\text{C}_6\text{H}_{13}\text{C}_6\text{H}_4\text{NO}_2$  as a yellowish oil 178° at 10 mm.; whence tin and  $\text{HCl}$  produce  $\text{C}_6\text{H}_{13}\text{C}_6\text{H}_4\text{NH}_2$  (175° at 15 mm.).

**n-HEPTYL BROMIDE**  $\text{C}_7\text{H}_{15}\text{Br}$ . *Bromoheptane*. (179°). S.G. 22° 1133. From *n*-heptyl alcohol and  $\text{HBr}$  (Cross, C. J. 32, 123).

**Sec-heptyl bromide**  $\text{C}_7\text{H}_{15}\text{CHBrCH}_3$ . (167°). S.G. 22° 1422. Prepared by the action of bromine on boiling *n*-heptane (Venable, B. 13, 1649). Colourless liquid.

**Tert-heptyl bromide**  $\text{Me}_2\text{C.CMe}_2\text{Br}$ . (150°). From penta-methyl-ethyl alcohol and  $\text{PBr}_3$  (Kaschirski, C. O. 1881, 278). Formed also from  $\text{Me}_2\text{C.CH.CHMe}_2$  and  $\text{HBr}$ . Solid, sol. alcohol, v. e. sol. ether.

**n-HEPTYL CHLORIDE**  $\text{C}_7\text{H}_{15}\text{Cl}$  i.e.  $\text{CH}_3(\text{CH}_2)_5\text{CH}_2\text{Cl}$ . *Chloroheptane*. (159°). S.G. 22° 881. From *n*-heptyl alcohol and  $\text{HCl}$  (C. F. Cross, C. J. 32, 123). Formed also, together with  $\text{CH}_3(\text{CH}_2)_5\text{CHClCH}_3$ , by chlorinating heptane from *Pinus Sabiniana*.

**n-Sec-heptyl chloride**  $\text{C}_7\text{H}_{15}\text{Cl}$  i.e.  $\text{CH}_3(\text{CH}_2)_4\text{CHClCH}_3$ . Formed as above (Schorlemmer a. Thorpe, A. 217, 150). Not obtained free from the preceding, the mixture of the two boiling between 143° and 158°. When chlorine acts upon *n*-heptane (98°), from petroleum, a mixture of heptyl chlorides (145°–160°) is obtained (Schorlemmer, C. J. 26, 319; cf. Pelouze a. Cahours, A. Ch. [4] 1, 5). When passed over heated lime this mixture of chlorides gives a mixture of heptylenes (96°–99°), with one of which  $\text{HCl}$  combines in the cold, forming a sec-heptyl chloride (188°–142°) (Morgan, A. 177, 307).

**Heptyl chloride**  $\text{C}_7\text{H}_{15}\text{Cl}$ . By chlorinating the isoheptane (96°) in petroleum, there is obtained a mixture of heptyl chlorides (144°–158°), whence  $\text{KOAc}$  forms a mixture of heptyl acetates (160°–185°), whence a mixture of a primary and a secondary heptyl alcohol may be got (Schorlemmer).

**Heptyl chloride**  $\text{C}_7\text{H}_{15}\text{Cl}$ . By chlorinating isoheptane  $\text{Pr.CH}_2\text{Pr}$  there is formed a mixture of heptyl chlorides (140°–150°), whence  $\text{KOAc}$  gives a mixture of acetates (160°–175°), from which a primary and a secondary heptyl alcohol may be obtained (Schorlemmer).

**Sec-heptyl chloride**  $\text{Pr.CH}_2\text{CH}_2\text{CHMeCl}$ . (136°). From the corresponding alcohol and  $\text{HCl}$  (Rohn, A. 190, 312).

**Tert-heptyl chloride**  $\text{CMe}_2\text{CMe}_2\text{Cl}$ . (135°) (K.); (123°) (E.). From the corresponding alcohol and  $\text{PCl}_5$  (Butlerow, A. 177, 176; Kaschirski, C. O. 1881, 278; Eltekoff, J. R. 14, 384). Small crystals. With aqueous  $\text{AgNO}_3$  it gives a pp. of  $\text{AgCl}$ .

**Tert-heptyl chloride**  $\text{CMeEtPrCl}$ . (135°–138°). S.G. 22° 899. From the alcohol and  $\text{HCl}$  (Kaschirski, J. R. 13, 90).

**n-HEPTYLENE**  $\text{C}_7\text{H}_{14}$  i.e.  $\text{CH}_3(\text{CH}_2)_5\text{CH=CH}_2$ . *n-Amyl-ethylene*. Mol. w. 98. (99°). S.G. 22° 703. Formed from *n*-heptane (of petroleum) by chlorinating, and heating the resulting mixture of heptyl chlorides with  $\text{KOAc}$  and  $\text{Ac}_2\text{O}$  at 160° (Schorlemmer, C. J. 26, 322), or by passing them over heated lime (Morgan, C. J. 26, 303). The mixture of heptylenes so obtained is treated with  $\text{HCl}$ , which combines only with  $\psi$ -heptylene leaving *n*-heptylene free. *n*-Heptylene occurs amongst the products formed in the preparation of oil gas (Armstrong, C. J. 49, 74). *n*-Heptylene combines with  $\text{HCl}$  when heated with fuming  $\text{HClAq}$  at 120°. With hydriodic acid at 120° it forms  $\text{C}_7\text{H}_{15}\text{CH}_2\text{CH}_2\text{I}$ . With water it forms, according to Le Bel (C. R. 61, 967), a hydrate, which is resolved by heat into water, a resin, and an unsaturated alcohol (140°).

**$\psi$ -Heptylene**  $\text{C}_7\text{H}_{14}$  i.e.  $\text{CH}_3\text{CH=CHCH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ . (98.5°). The mixture of chloroheptanes from the heptane of *Pinus Sabiniana*, containing  $\text{CH}_3(\text{CH}_2)_4\text{CH}_2\text{CHCl}$  and  $\text{CH}_3(\text{CH}_2)_3\text{CHClCH}_2\text{CH}_3$ , if heated with alcoholic  $\text{KOH}$  at 100° forms a mixture of heptylenes and ethyl heptyl oxides. The heptylene, purified by distilling over sodium, boils at (98.5°). This heptylene, placed with fuming  $\text{HCl}$  in the dark for six weeks, is but slightly affected, only 10 p.c. combining. On the other hand, petroleum heptylene combines under the same conditions to the extent of 50 p.c. But after several months the first heptylene (from *Pinus*) is almost completely combined with  $\text{HCl}$ , while more of the

petroleum heptylene has combined. Thus cold HCl will not separate isomeric olefines. *Pinus* heptylene is oxidised by  $H_2SO_4$  and  $K_2Cr_2O_7$  to valeric and acetic acids only (Schorlemmer & Thorpe, A. 217, 151; cf. Venable, A. C. J. 4, 22). It rapidly absorbs ClOH in the cold (Grissom, Am. 10, 225).

Heptylene  $C_7H_{14}$ , from heptylidene chloride and sodium (Limprieh, A. 103, 86).

*Iso*-heptylene  $Pr.CH_2.CH(CH_3).CH_2$ . (91°). S.G. 1.706. From  $EtO.C_7H_{13}$ , by chlorinating and heating the resulting mixture of heptyl chlorides with KOAc and  $Ac_2O$  at 160° (Grimshaw, C. J. 26, 313). The product, however, is probably a mixture; for a part only combines in the cold with HCl.

Heptylene  $C_7H_{14}$ , i.e.  $Pr.CH_2.CH_2.CH(CH_3).CH_2$ ? (75°-80°). From  $Pr.CH_2.CH_2.CH(CH_3).CH_2$  and alcoholic KOH (Rohr, A. 190, 314).

Heptylene  $C_7H_{14}$ . (91°). From the isohexane in petroleum (Schorlemmer, C. J. 26, 320).

*ψ*-Heptylene  $Pr.CH_2.CMe_2$ , or  $Pr.CH_2.CMe.CH_2$ . (84°). S.G. 1.7144. From di-methyl-isobutyl-carbinyl iodide and alcoholic KOH at 100° (Pawloff, A. 173, 194). Unites with  $H_2$ , reproducing the parent iodide.

Heptylene  $Pr.CH.CMe_2$ . (82°). S.G. 1.6995. From oxy-iso-octioic acid  $(C_7H_{13})_2C(OH).CO_2H$  by heating with water and a few drops of  $H_2SO_4$  at 180° (Markownikoff, Z. 1871, 268). Unites with  $H_2$ , forming  $Pr.CMe_2.I$ , and is perhaps identical with the preceding heptylene.

Heptylene  $CMe_2.CMe.CH_2$ . (80°). From  $CMe_2.CMe.I$  and alcoholic KOH (Butlerow, J. R. 7, 44; Kaschirski, C. C. 1881, 278). Formed also by heating  $CMe_2.CHMe$  with MeI and PbO at 225° (Eitckoff, J. R. 14, 382; B. 16, 395). Combines with  $H_2$ , forming  $CMe_2.CMe.I$ .

Heptylene  $CMe_2.CMeEt$ . (75°-80°) (Pawloff, A. 188, 122); (92°-95°) (Kaschirski, C. C. 1881, 278). S.G. 1.7355;  $d_4^{20}$  1.7188 (K.). From  $MeEtPrC.OH$ .

Heptylene  $HCEt.CMeEt$ ? (90°-95°). From  $MeEtPrC.OH$  (17°). Socoloff (J. R. 1887, 537) among the products of the oxidation of  $CMeEtPrOH$  found a heptylene (97°), S.G. 2.718 which on further oxidation yielded acetic and propionic acids but no ketone.

Heptylene  $C_7H_{14}$ . (96°). S.G. 742. Occurs in the product of the distillation of colophony, and separated from toluene by sulphonating the latter (Renard, Bl. [2] 39, 546; cf. C. R. 91, 419; Emmerling, B. 12, 1441).

Heptylenes have also been obtained with the following boiling-points: (a) by strongly heating paraffin (94°-97°) (Thorpe & Young, A. 165, 11); (b) by heating heptioic aldehyde with lime (95°-100°) (Fittig, A. 117, 77); (c) by heating fusel oil with  $ZnCl_2$  (80°-85°) (Wurtz, Bl. 5, 307); (d) by distilling a lime soap formed from train oil (94° cor.) (Warren & Storer, Z. 1868, 229).

Reference.—BROMO-HEPTYLENE.

HEPTYLENE BROMIDE v. DI-BROMO-HEPTANE.

HEPTYLENIC ACID v. HEPTENOIC ACID.  
DI-HEPTYL-HEPTOIC ALDEHYDE v. HEN-  
NOENOIC ALDEHYDE.

HEPTYL HYDRIDE v. HEPTANE.

HEPTYLIC ACID v. HEPTOIC ACID.

HEPTYLIDENE. The radical  $C_7H_{13}.CH$ .

HEPTYLIDENE DI-ACETONAMINE v. ACETONAMINE.

HEPTYLIDENE-DI-AMINE *Di-benzoyl derivative*  $C_7H_{13}.N_2O_2$ , i.e.  $C_7H_{13}.CH(NH.Bz)_2$ . [128°]. Formed by heating heptioic aldehyde with benzamide (Medicus, A. 157, 44). Insol. water, HClAq, and KOH; sl. sol. boiling ether, v. sol. boiling alcohol. Split up by boiling HClAq into benzamide and heptioic aldehyde (enanthalol).

*Di-nitro-di-benzoyl derivative*  $C_7H_{13}.CH(NH.CO.C_6H_5.NO_2)_2$ . [170°]. From heptioic aldehyde and nitro-benzoic aldehyde.

HEPTYLIDENE BROMIDE v. DI-BROMO-HEPTANE.

HEPTYLIDENE CHLORIDE v. DI-CHLORO-HEPTANE.

HEPTYLIDENE THIOCARBIMIDE

$C_7H_{13}.CH(NCS)_2$ . From  $C_7H_{13}.CH(NH.CS.NH_2)_2$ , by warming with alcohol and HCl (H. Schiff, B. 11, 833). Oil, with disgusting odour. Combines with  $NH_3$ , reproducing the parent substance.

HEPTYLIDENE-DI-THIO-DI-UREA

$C_7H_{13}.N_2O_2$ , i.e.  $C_7H_{13}.CH(NH.CS.NH_2)_2$ . Formed by adding a drop of HCl to an alcoholic solution of thio-urea and heptioic aldehyde (enanthalol) (H. Schiff, B. 11, 833). Decomposed by HCl forming the preceding body.

HEPTYLIDENE-DI-UREA  $C_7H_{13}.N_2O_2$ , i.e.  $C_7H_{13}.CH(NH.CO.NH_2)_2$ . [166°]. Formed by adding heptioic aldehyde (enanthalol) to an alcoholic solution of urea. Small needles; v. sl. sol. alcohol and ether. Decomposed by heat. Boiling dilute acids split it up into urea and heptioic aldehyde. When warmed with an alcoholic solution of benzoic aldehyde there is formed  $C_7H_{13}.CH(NH.CO.NH.CH(C_6H_5).NH.CO.NH_2)_2$ ; a powder insol. water, sl. sol. alcohol and ether (Schiff, A. 151, 195).

Di-heptylidene-tri-urea  $C_7H_{13}.N_3O_3$ , i.e.  $(NH_2.CO.NH.CH(C_7H_{13}).NH)_2.CO$ . [162°].

Formed by tritulating urea with heptioic aldehyde. Crystalline powder. Boiling dilute acids convert into it urea and heptioic aldehyde. Benzoic aldehyde forms  $C_7H_{13}.CH(NH.CO.NH.CH(C_6H_5).NH.CO.NH.CH(C_7H_{13}).NH.CO.NH)_2$ ; a gelatinous substance that swells up in water (Schiff).

Tri-heptylidene-tetra-urea  $C_7H_{13}.N_4O_4$ . [155°]. Formed, together with penta-heptylidene-hexa-urea  $C_7H_{13}.N_5O_5$  [c. 150°], by heating either of the preceding uroids with heptioic aldehyde at 100°. Amorphous yellow powder; insol. water, sl. sol. alcohol and ether. Swells up in cold water (Schiff & cf. Leeds, B. 16, 293, who questions the above formulae).

*n*-HEPTYL IODIDE  $C_7H_{15}.I$  i.e.  $CH_3(CH_2)_5CH_2.I$ . (203.8°). S.G. 1.4008. S.V. 198.6. C.E. (0°-10°) 0.0091. From *n*-heptyl alcohol and HI (Cross, A. 189, 4; Dobriner, A. 243, 28).

*n*-Sec-heptyl iodide  $CH_3(CH_2)_4CH(CH_3).I$ . (98° at 50 mm.). From the corresponding bromide by treatment with KI (Venable, B. 13, 1647). Converted by NaOEt into heptylene. When distilled under atmospheric pressure it splits up into HI and heptylene.

Heptyl iodide  $C_7H_{15}.I$ . (170°). Obtained from heptylene (from petroleum heptane) and HI at 100° for 12 hours (Schorlemmer, C. J. 16, 320).

Heptyl iodide  $C_7H_{15}.I$ . (190°). Obtained by the action of iodine and phosphorus on the

heptyl alcohol derived from heptane of petroleum (Schorlemmer, *C. J.* 16, 219; cf. Petersen, *A.* 118, 74). Heavy oil; alcoholic  $\text{AgNO}_3$  separates the whole of its iodine as  $\text{AgI}$ .

Heptyl iodide  $\text{C}_7\text{H}_{15}\text{I}$  i.e.  $\text{Pr.CHI}$ . (180°) (K.). (185°) (F.). S.G.  $\frac{2}{3}$  1.2. From di-propyl-carbinol, I, and P (Kurtz, *A.* 161, 205; Friedel, *A. Ch.* [4] 16, 310).

Heptyl iodide  $\text{C}_7\text{H}_{15}\text{I}$  i.e.  $\text{Pr.CH}_2\text{CMe}_2\text{I}$ . From di-methyl-isobutyl-carbinol and HI (Fawloff, *A.* 178, 192). Also from  $\text{Me}_2\text{CH.OH.CMe}_2$  and HI. Heavy oil.

Heptyl iodide  $\text{CMe}_2\text{CMe}_2\text{I}$ . [142°]. From the alcohol and HI (Butlerow, *A.* 177, 184; Kaschirski, *C. C.* 1881, 278). Solid, smelling like camphor.

Heptyl iodide  $\text{Pr.CH}_2\text{CH}_2\text{CH}_2\text{I}$  Me. (165°-175°). From the alcohol and iodide of phosphorus (Rohn, *A.* 190, 313).

Heptyl iodide  $\text{MeEtPrCl}$ . (146°). S.G.  $\frac{2}{3}$  1.93;  $\frac{2}{3}$  1.378. From the alcohol and HI (Kaschirski, *J. R.* 13, 90). Suffers much decomposition when distilled.

DI-HEPTYLKETONE  $\text{C}_{12}\text{H}_{22}\text{O}$  i.e.  $(\text{C}_7\text{H}_{13})_2\text{CO}$ . [40°]. (178°). Obtained by distilling barium octoate (caprilate) with excess of lime (Guckelberger, *A.* 69, 201). Waxy solid.

*n*-SEC-HEPTYL-MALONIC ACID  $\text{C}_{12}\text{H}_{20}\text{O}_4$  i.e.  $\text{C}_7\text{H}_{13}\text{CHMe.CH(CO}_2\text{H)}_2$ . [98° uncor.]. White crystals. Sol. alcohol, chloroform, and ether, sl. sol. water.

Salts (Leeds, *A. C. J.* 5, 10).— $\text{Ba}^+$ : white powder, insol. water and alcohol.— $\text{Cu}^+$ : light-blue crystals, sl. sol. water, sol. alcohol.— $\text{Pb}^+$ : [235°]. White mass, insol. water, sl. sol. alcohol.— $\text{Zn}^+$ : [247°]; minute crystals.— $\text{Ag}^+$ : [244°]; minute crystals, insol. boiling water.

Ethyl ether A.Et. (263°-265°). Colourless liquid. Prepared by the action of *n*-sec-heptyl iodide and sodium on a mixture of alcohol and malonic ether. On heating the acid to 160° it gives heptyl-acetic acid and  $\text{CO}_2$  (Venable, *B.* 13, 1651).

HEPTYL OCTYL OXIDE  $\text{C}_{15}\text{H}_{32}\text{O}$  (278-8°). S.G.  $\frac{2}{3}$  8182. S.V. 376-8. O.E. (0°-10°) 00085 (Dobriner, *A.* 243, 10).

DI-HEPTYL-OXIDE  $(\text{C}_7\text{H}_{13})_2\text{O}$ . (261-9°). S.G.  $\frac{2}{3}$  8152. S.V. 352-7. C.E. (0°-10°) 00098 (Dobriner, *A.* 243, 9).

HEPTYL-UREA Octoyl derivative  $\text{C}_7\text{H}_{15}\text{NH.CO.NH.CO.C}_7\text{H}_{15}$ . [102°]. Formed by the action of an alkaline solution of bromine on octoic amide (Hofmann, *B.* 15, 760; 17, 1408).

HERACLEUM OIL. The essential oil of the cow-paranep (*Heracleum Sphondylium*) is light-green, mobile, S.G.  $\frac{2}{3}$  864, and consists mainly of octyl acetate (200°-242°), whence by saponification octyl alcohol (191°) may be obtained. The portions boiling at a higher temperature contain octyl hexoate (270°) (Zihcke, *A.* 152, 1). The oil also contains ethyl butyrate, hexyl acetate, octyl decanoate, and octyl laurate in small quantities (Möslinger, *A.* 185, 26). The water with which the oil has been distilled contains methyl alcohol, ethyl alcohol (in smaller quantity), acetic acid, and caproic acid.

The volatile oil of *Heracleum giganteum* is a mixture of octyl acetate, hexyl butyrate, and ethyl butyrate (Franchimont & Zincke, *B.* 4, 322; *A.* 163, 198; Gutzeit, *A.* 177, 344).

HERACLIN  $\text{C}_{25}\text{H}_{50}\text{O}_{12}$ . [185°]. S. (alcohol) 14 in the cold; 1.7 at 78°. S. (CS<sub>2</sub>) 0.83 in the cold; 2.5 at 46°. Occurs in the seeds of *Heracleum giganteum* (Gutzeit, *J.* 1879, 905). Silky needles (from alcohol). Insol. water, v. sol. chloroform, m. sol. ether.

HESPERETIC ACID v. ISOFERULIC ACID.

HESPERETIN v. HESPERIDIN.

HESPERETOL

$\text{C}_9\text{H}_7(\text{OMe})(\text{OH}).\text{CH}:\text{CH}_2$  [4:3:1]. [57°]. Prepared by the dry distillation of calcium isoferulate (Tiemann & Will, *B.* 14, 967). Crystalline solid, sol. alcohol and ether. Dissolves in caustic alkalis. Gives a red colouration with  $\text{H}_2\text{SO}_4$ .

HESPERIC ACID  $\text{C}_{22}\text{H}_{34}\text{O}_6$ . An acid which may be extracted by alcohol from orange-peel (Tanret, *Bl.* [2] 46, 500). Slender white crystals; not volatile; insol. water and ether, sl. sol. cold alcohol, sol. boiling (90 p.c.) alcohol and chloroform. Its K, Na, and Ca salts are amorphous, and decomposed by  $\text{CO}_2$ — $\text{Ca}^+$ .

HESPERIDENE  $\text{C}_{15}\text{H}_{24}$ . (178° cor.). S.G.  $\frac{2}{3}$  846. A terpene contained in the volatile oil of orange-peel (Wright, *C. J.* 26, 549). It forms a tetrabromide  $\text{C}_{15}\text{H}_{24}\text{Br}_4$  [105°], and with  $\text{NOCl}$  a nitroso-derivative [71°]. Identical with citrene, carvene, limonene, &c. (v. TERPENES).

HESPERIDIN  $\text{C}_{27}\text{H}_{42}\text{O}_{12}$  (T. a. W.), or  $\text{C}_{26}\text{H}_{40}\text{O}_{12}$  (Tanret). [251°]. S. (hot water) 0.2 (Hilger, *B.* 9, 26); 1.3 at 100° (T.); S. (alcohol) 5 in the cold; 1.8 at 78°; S. (EtOAc) 67 (Tanret, *Bl.* [2] 46, 502).  $[\alpha]_D^{20} = -89^\circ$ . Discovered by Lebreton (*J. Ph.* 14, 377) in many fruits of the genus *Citrus*; thus it may readily be obtained from the white spongy inner coating of the peel of unripe Seville oranges, or from dry unripe bitter oranges (*Citrus Bigaradia*).

Preparation.—Dried unripe orange-peel is thoroughly extracted with water to remove other substances, and the residue then dissolved out with dilute alcoholic NaOH; the impure hesperidin is pptd. from the solution by adding HCl and purified by extraction with alcohol, solution in NaOH, and reppn. with  $\text{CO}_2$ ; the yield is at most 10 p.c. (Tiemann & Will, *B.* 14, 946).

White minute hygroscopic needles. Nearly insol. alcohol and water, insol. ether. Weak acid, dissolving in aqueous NaOH. It does not react with  $\text{AcCl}$ , or form a compound with picric acid (Paternò & Briosi, *G.* 6, 169).

Reactions.—1. On reduction with sodium amalgam it gives a body which dissolves in alcohol with a magenta-like colour.—2. By boiling dilute  $\text{H}_2\text{SO}_4$  it is split up into sugars and hesperitin ( $\text{C}_{16}\text{H}_{26}\text{O}_{12}$ ). The sugar obtained is a mixture of 2 pts. of glucose with 1 pt. of isodulcitol (Tanret, *Bl.* [2] 49, 20); these sugars may be separated by means of their phenyl-hydrazides, that of isodulcitol [180°] being soluble in acetone (Will, *B.* 20, 1386).—3. Hesperidin dissolves in dilute KOH, the solution becoming gradually yellow; if it be evaporated to dryness, and the residue be treated with dilute  $\text{H}_2\text{SO}_4$ , it is turned red, and afterwards violet.—4. Potash-fusion forms protocatechuic acid.

Hesperetin  $\text{C}_{16}\text{H}_{26}\text{O}_{12}$  i.e.  $[\text{4:3:1}]\text{C}_9\text{H}_7(\text{OMe})(\text{OH}).\text{CH}:\text{CH}.\text{CO}.\text{O}.\text{C}_6\text{H}_4(\text{OH})$  [1:3:5]? [226°]. Prepared by heating hesperidin with dilute  $\text{H}_2\text{SO}_4$  to 120° (E. Hoffmann, *B.* 9, 687; Tiemann & Will, *B.* 14, 951). White plates.

7. sol. alcohol, m. sol. ether, al. sol. water, benzene, and chloroform. Weak phenolic acid, dissolving in NaOH, ppd. by  $\text{CO}_2$ . Has a sweet taste. Like hesperidin, on reduction with sodium-amalgam it gives a substance which dissolves in alcohol forming a magenta-like solution. On boiling with aqueous KOH it decomposes into phloroglucin and isoferulic acid (hesperetic acid).  $\text{FeCl}_3$  gives a brownish-red colour. Lead acetate gives a pp. Potash-fusion yields protocathechuic acid.

Iso-hesperidin  $\text{C}_{27}\text{H}_{42}\text{O}_{12} \cdot 2\text{aq}$  or  $\text{C}_{26}\text{H}_{40}\text{O}_{12} \cdot 5\text{aq}$ .  $[\alpha]_D^{20} = -89^\circ$ . S. 200 at  $100^\circ$ . S. (96 p.c. alcohol) 11 in the cold. Obtained from orange-peel by extracting with (60 p.c.) alcohol, evaporating, and shaking the residue with chloroform (Tanret, *Bl.* [2] 46, 502; 49, 20). Minute needles from water (containing 2aq), with slightly bitter taste. S. sol. cold water, v. e. sol. hot water. Levorotatory. Split up by boiling dilute  $\text{H}_2\text{SO}_4$  into hesperidin, dulcitol, and glucose. The substance called hesperidin by De Vrij is described as NARINGIN.

#### HETERO-ALBUMOSE v. PROTEIN.

**HEVEENE**  $\text{C}_{15}\text{H}_{24}$ ? (315°). S.G. 21-921. The least volatile part of the product of the dry distillation of caoutchouc and gutta-percha (Bouchardat, *A.* 27, 30). Ambra-yellow oil. Miscible with alcohol and ether. HCl forms unstable  $\text{C}_{15}\text{H}_{24}\text{HCl}$ . V. TERPENES.

**n-HEXADECANE**  $\text{C}_{16}\text{H}_{34}$ . *Hexadecane. Di-octyl.* [14°] (E.); [18°] (K.); [20°] (L.); [21°] (Z.). (150° at 10 mm.; 209° at 100 mm.; 288° at 760 mm.); (278°) (Z., S.); (158° at 15 mm.) (K.). S.G. 2° 774; 122° 719. Odourless solid. Formed by reduction of palmitic acid with P and HI (Kraft, *B.* 15, 1701; 16, 1722; 19, 2218). Also from n-octyl iodide and sodium (Lachovitch, *A.* 220, 180; cf. Zincke, *A.* 152, 15; Kraft, *B.* 19, 2222) and by heating  $\text{H}_2(\text{C}_8\text{H}_{17})_2$  at 200° (Eichler, *B.* 12, 1882). Probably the same hydrocarbon [20°], (278°), V.D. 7-9, is formed by digesting an alcoholic solution of cetyl iodide with zinc and fuming HCl for a week (Sorabji, *C. J.* 47, 37). Pearly plates, sol. hot alcohol and ether.

**Hexadecane**  $\text{C}_{16}\text{H}_{34}$ . *CHMe.CHMe.C}\_8\text{H}\_{17}. *Di-iso-octyl.* (263°-265°) (L.); (269° oor.) (A.). S.G. 2° 800 (L.); 2° 802 (A.). V.D. 114.3 (for 113). From secondary octyl bromide (or iodide) and sodium. Liquid smelling of freshly extinguished tallow candles (Lachovitch, *A.* 220, 187; cf. Alechin, *Bl.* [2] 40, 186).*

**Hexadecane**  $\text{C}_{16}\text{H}_{34}$ . *Cetyl hydride. Cetane.* (280°). V.D. 8.08 (calc. 7.96). Obtained from American petroleum by fractional distillation (Pelouze & Cahours, *C. R.* 57, 62). Probably identical with n-hexadecane.

*Reference.*—DI-BROMO-HEXADECANE.

**HEXADECIC ACID**  $\text{HC}(\text{C}_8\text{H}_{17})_2\text{CO}_2\text{H}$ . *Di-n-heptyl-acetic acid.* (26°). (240°-250°) at 80-90 mm. Obtained by decomposing its ether with concentrated alkalis. Crystalline. Insol. water, sol. alcohol or ether.

**Salts.**—The salts of the alkalis are soapy and v. sol. water or alcohol. The salts of the alkaline earths and heavy metals have a great tendency to form basic salts.— $\text{BaA}_2$ : slender needles (from alcohol); insol. water.— $\text{CuA}_2$ : bluish-green crystalline pp. [227°].

*Ethyl ether EtA'*. (c. 810°). From heptyl-

aceto-acetic ether, NaOEt, and heptyl iodide (Jourdan, *A.* 200, 114). Oil.

*Isomeride v. PALMITIC ACID.*

**HEXADECYL**. The radical  $\text{C}_{16}\text{H}_{33}$ , also called **CETYL** (q. v.).

**HEXADECYL ALCOHOL** v. **CETYL ALCOHOL**.

**HEXADECYL ALLOPHANATE**

$\text{C}_{16}\text{H}_{33}\text{O} \cdot \text{O} \cdot \text{CO} \cdot \text{NH} \cdot \text{CO} \cdot \text{NH}_2$ . [70°]. Formed by the action of chloro-formamide on an ethereal solution of cetyl alcohol (Gattermann, *A.* 244, 41). Colourless plates (from alcohol).

**HEXADECYL-BENZENE**  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_5$ . [27°]. (230° at 15 mm.). S.G. 2° 8567. From cetyl iodide, iodobenzene, and Na. Sl. sol. cold alcohol, v. sol. ether, benzene,  $\text{CS}_2$ , and chloroform (Kraft & Götting, *B.* 19, 2683; 21, 3180). Gives a nitro-derivative [36°] which reduces to  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2$  [53°] (255° at 14 mm.) whence  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{NHAc}$ . [104°].

**HEXADECYL-CRESOL**  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me} \cdot \text{OH}$ . [62°]. (268°). Formed from p-hexadecyl-toluene sulphonic acid by potash-fusion at 150°. Crystals (from alcohol).

*Ethyl ether*  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me} \cdot \text{OEt}$ . [26-5°]. From hexadecyl-cresol, ethyl iodide, and alcoholic KOH (Kraft & Götting, *B.* 21, 3180).

**HEXADECYLENE** v. **CETENE**.

**HEXADECYLENE BROMIDE** v. **DI-BROMO-HEXADECANE**.

**HEXADECYL-MESITYLENE**

$\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_3 \cdot \text{Me}_3$  [6:5:3:1]. [c. 40°]. (258° at 15 mm.). From bromo-mesitylene, cetyl iodide, and sodium (Kraft & Götting, *B.* 21, 3180).

**HEXADECYL-PHENOL**  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{OH}$ . [77-5°]. (261° at 15 mm.). From hexadecylbenzene by sulphonating and treating the resulting sulphonic acid with KOH (Kraft, *B.* 19, 2683; 21, 3180).

*Ethyl derivative*  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{OEt}$ . [43°]. Plates; gives on oxidation [4:1]  $\text{C}_6\text{H}_4(\text{OEt})(\text{CO}_2\text{H})$ .

**o-HEXADECYL-TOLUENE**

$\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$  [1:2]. [9°]. (239° at 15 mm.). S.G. 2° 8676; 2° 8072. From o-bromo-toluene, cetyl iodide, and sodium (Kraft & Götting, *B.* 21, 3181).

**m-Hexadecyl-toluene**  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$  [1:3]. [12°]. (237° at 15 mm.). From m-bromo-toluene, cetyl iodide, and Na (K. & G.).

**p-Hexadecyl-toluene**  $\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$  [1:4]. [27-5°]. (240° at 15 mm.). Converted by  $\text{HNO}_3$  (S.G. 1-2) at 125° into p-toluic acid. Fuming  $\text{H}_2\text{SO}_4$  sulphonates it.

**HEXADECYL-m-XYLENE**

$\text{C}_{16}\text{H}_{33} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}_2$  [4:3:1]. [33-5°]. (250°). From bromo-m-xylene, cetyl iodide, and sodium. Crystallises from ether-alcohol (Kraft & Götting, *B.* 21, 3180).

**HEXA-ICOSANE**  $\text{C}_{26}\text{H}_{54}$ . [44°]. A soft wax; substance found among the products of the distillation of cerotic acid (Nafziger, *A.* 224, 266).

**HEXAM DECA-CARBOXYLIC ETHER** v.

**HEXANE DECA-CARBOXYLIC ACID.**

**HEXAMIDINE**  $\text{C}_6\text{H}_{12}\text{N}_4$ , i.e.

$\text{Pr} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{C}(\text{NH}_2)_2 \cdot \text{NH}_2$ . *Capronamidin*

Heated with acetic anhydride and sodium acetate it yields the nitrile of hexoic (caproic) acid.

**Salts.**— $\text{BHCl}$ : large plates [107°], v. so alcohol.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6$ : yellowish-red plate [199°], sol. hot, al. sol. cold, water (Pinner, *J.* 17, 175).

**HEXAMIDOXIM**  $C_6H_{11}C(NO_2)NH_2$ . *Capramidoxim*. *Isobutylacetamidoxim*. [58°]. Formed by direct combination of hexopitrile (capronitrile) with hydroxylamine. Glistening white silvery tables. V. sol. alcohol, ether, &c., al. sol. water. Dissolves in aqueous acids and alkalis.— $B^*HCl$ : [116°]; white needles, v. sol. water and alcohol, al. sol. ether.

*Ethyl ether*  $C_6H_{11}C(NH_2)NOEt$ : [35°]; very hygroscopic, long white needles; v. sol. alcohol, ether, &c., al. sol. water.

*Acetyl derivative*  $C_6H_{11}C(NH_2)NOAc$ : [37°]; very fine silky white scales; v. sol. alcohol and ether, nearly insol. water.

*Benzoyl derivative*  $C_6H_{11}C(NH_2)NOBz$ : [106°]; felted white needles; sol. alcohol, ether, and benzene, insol. water.

*Hexoyl derivative*  $C_6H_{11}C(NH_2)NOCO_2C_6H_{13}$ : [115°]; silvery scales; v. sol. alcohol, ether and benzene, al. sol. water.

*Carbonyl derivative*  $(C_6H_{11}C(NH_2)NO)_2CO$ : [114°]; felted silky needles; v. sol. alcohol and chloroform, nearly insol. water and benzene. Formed by the action of carbonyl chloride upon hexamidoxim (Jacoby, B. 19, 1500).

*n*-HEXANE  $C_6H_{14}$ , i.e.  $CH_3CH_2CH_2CH_2CH_2CH_3$ . *Di-n-propyl. Hexyl hydride*. *Methyl-pentane*. *Methyl-amyl. Ethyl-butane*. *Ethyl-butyl*. Mol. w. 86. (68.7°) at 751 mm. (Schiff, A. 220, 88); (69.0° i.V.) (Zander, A. 214, 165); (68.6°) at 744 mm. (Brühl, A. 200, 184); (69°) (Perkin, C. J. 45, 446). V.D. 8.06 (calc. 2499) (Schiff). S.G.  $\frac{20}{4}$  6753 (Z.);  $\frac{15}{4}$  6603 (B.);  $\frac{15}{4}$  6668 (S.);  $\frac{1}{2}$  6739;  $\frac{2}{3}$  6662 (P.). M.M. 6.670 at 11° (P.). S.V. 139.7 (Schiff); 140 (Z.); 138.7 (Ramsay).  $\mu_2$  1.3799.  $R_D$  47.59 (B.). Critical temperature 250.3° (Pawlewsky, B. 16, 2634). Occurs in Pennsylvanian petroleum, in the light oils from coal tar (Schorlemmer, T. 162, 111), and in Galician petroleum (Lachovitch, A. 220, 192). Is the chief constituent of so-called 'petroleum ether' or 'ligroin.'

*Formation*.—1. By reducing with zinc and dilute HCl the *sec*-hexyl iodide derived from mannite; the product being freed from hexylene by treatment with bromine (Schorlemmer; cf. Erlenmeyer, Z. 1863, 274).—2. By heating *n*-propyl iodide dissolved in ether with sodium at 145° (Schorlemmer, A. 161, 277).—3. By distilling suberic acid with lime or baryta (Dale, C. J. 17, 258; cf. Riche, A. 113, 106).—4. Among the products obtained by distilling tri-olein under pressure (Engler, B. 22, 596).

*Properties*.—Oil, with faint characteristic odour, unlike petroleum.

*Reactions*.—1. On passing through a red-hot tube the following products were obtained: ethylene, propylene, butene  $C_4H_8$ , amylene, hexylene, benzene, and gases not absorbed by bromine. Decomposition begins at 600° to 700°. *hex* benzene is not formed except at a high temperature (Norton A. Andrews, Am. 8, 1).—2. Chlorination gives  $CH_3CH_2CH_2CH_2CH_2CH_2Cl$  and  $CH_3CH_2CH_2CH_2CHClCH_3$  (Schorlemmer, A. 199, 189; cf. Morgan, C. J. 28, 801).—3. Bromine vapour passed through boiling hexane forms only secondary hexyl bromide (Schorlemmer, T. 1878, 1; A. 188, 250). Bromine at 125° forms crystalline  $C_6H_{13}Br$ , and also  $C_6H_5Br$ ,

and  $C_6H_5Br$ ; at 135° it forms  $C_6Br_6$ , which, at a higher temperature, is resolved into bromine and hexa-bromo-benzene (Wahl, B. 10, 402, 1234).

*Sec-hexane*  $C_6H_{14}$ , i.e. *Pr.Pr. Isohexane Propyl-isopropyl. Ethyl-isobutyl. Methyl-isopropyl-propane*. (62°) (W.); (59°-62°) (Perkin, C. J. 45, 447). S.G.  $\frac{20}{4}$  701;  $\frac{15}{4}$  6633;  $\frac{2}{3}$  6534 (P.). M.M. 6.769 at 17° (P.). V.D. 8.05 (calc. 2.98). Prepared by decomposing isobutyl iodide (40 g.) with EtI (34 g.) and sodium (11 g.) (Wurtz, A. Ch. [3] 44, 276). Occurs in Galician and in American petroleum (Warren; Lachovitch, A. 220, 192). By passing through a red-hot tube it is decomposed into ethylene, propylene, butylene, amylene, hexylene, butene, and some paraffins (Norton A. Andrews, Am. 8, 1).

*Sec-hexane*  $C_6H_{14}$ , i.e. *Pr.Pr. Di-isopropyl. Isohexane*. (58.0°) (Zander, A. 214, 167). S.G.  $\frac{20}{4}$  6829 (Z.); 668 (Perkin, C. J. 45, 447). M.M. 6.784 at 15° (P.). S.V. 136.5 (Z.). Formed by the action of sodium on an ethereal solution of isopropyl iodide (Schorlemmer, A. 144, 184). Formed also by the action of HI on pinacone  $CMe_2(OH).CMe_2(OH)$  (Bouchardat, C. R. 74, 809). According to Berthelot (Bl. 9, 268) this hexane is also obtained by heating di allyl with  $HI$ . Riche (A. Ch. [5] 9, 432) obtained it by distilling barium *n*-heptoate at a red heat. It also occurs among the products obtained by distilling whale oil under pressure (Engler, B. 22, 596). It is an oil, with faint odour. Chromic acid oxidises it to  $CO_2$  and acetic acid.

*Sec-hexane*  $C_6H_{14}$ , i.e.  $CH_3CH_2CH_2CH_2CH_2CH_3$ . *Methyl-di-ethyl-methane*. (64°). S.G.  $\frac{20}{4}$  6765. One of the products of the reduction of  $CH_3CH_2CH_2CH_2CH_2CH_2Et$  with zinc and glacial acetic acid  $CH_3C(OH)Et$ , and  $CH_3CH_2CH_2CH_2CH_2Me$  being also formed (Wislicenus, A. 219, 315). The same hydrocarbon, (60°), was said by Le Bel (Bl. [2] 25, 546) to be formed, together with ethane and decane, by the action of sodium on a mixture of  $MeI$  and optically active amyl iodide; Junt (A. 220, 150) failed, however, to obtain it by this method.

*Tert-hexane*  $C_6H_{14}$ , i.e.  $CM_3Et$ . *Tri-methyl-ethyl-methane*. (43°-49°). From *tert*-butyl iodide and  $ZnEt_2$  (Goriainoff, A. 165, 107).

*References*.—Di-bromo- and Di-chloro-hexane.

**HEXANE CARBOXYLIC ACID v. HEPTOIC ACID.**

*Hexan* di-carboxylic acid v. *DI-ETHYL-SUCCINIC, TETRA-METHYL-SUCCINIC, AMYL-MALONIC, SUBERIC, and DI-ALDANIC ACIDS.*

*Hexane tri-carboxylic acid*  $CH_3CH_2(CO_2H).CH_2(CO_2H)_2$ . [160°]. *Ethyl-butanyl tri-carboxylic acid*. Formed by saponifying the ether (1 mol.) with  $KOH$  (3 mols.) to which a little alcohol has been added (Hjelt, B. 21, 2089). Crystalline solid, v. sol. water. At 150°-160° it is split up into  $CO_2$  and di-ethyl-succinic acid.

*Ethyl ether*  $Et_2A''$  (186° at 86 mm.); (281° at 760 mm.). S.G.  $\frac{20}{15}$  1.024.

*Formation*.—1. By the action of  $\alpha$ -bromobutyric ether on sodium ethyl-malonate ether (Hjelt, B. 21, 2089; cf. Hjelt, B. 20, 8078).—2. Sodium (11.5 g.) is dissolved in alcohol

200 c.c.) and butane tri-carboxylic ether  $\text{H}(\text{CO}_2\text{Et})_3\text{CH}(\text{CO}_2\text{Et})$  (137 g.) is added to ether with  $\text{EtI}$  (80 g.). The reaction is complete after heating at  $100^\circ$  for 4 hours (Bischoff, 3, 21, 2092).

**Properties.**—Oil, which distils with partial decomposition. By boiling with  $\text{H}_2\text{SO}_4$  it is saponified,  $\text{CO}_2$  being given off, and two isomeric di-ethyl-succinic acids formed, one being v. sol. ether, the other sl. sol. ether.

First nitrile  $\text{CO}_2\text{Et.CC}(\text{Et})\text{CH}(\text{CO}_2\text{Et})$ . (280°–286°). A product of the action of alcoholic  $\text{KCy}$  on  $\alpha$ -bromo-butyric ether (Zelinsky a. Britschinin, B. 21, 3398). Oil.

**Hexane tri-carboxylic acid**  $\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})_3$ . **Subero-carboxylic acid**. S. 35–6 at  $14^\circ$ . Formed by boiling chloro-suberic acid with  $\text{KCy}$  and decomposing the resulting cyano-suberic acid with  $\text{KOH}$  (Gröger, M. J. 510; Bauer, M. 4, 341).— $\text{Pb}_2\text{A}''$  (at  $100^\circ$ ).— $\text{FeA}'''$  brown pp.— $\text{Ag}_2\text{A}''$ .

**Hexane tetra-carboxylic acid**. **Ethyl ether**  $\text{CH}_3(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2$ . **Di-ethyl-acetylene-tetra-carboxylic ether**. (199° at 11 mm.). S.G.  $\frac{12}{15}$  1.043. Formed from chloro-ethyl-malonate ether and sodium ethyl-malonate (Bischoff, B. 21, 2085). Oil. On saponification it yields di-ethyl-succinic acid (188°).

**Hexane deca-carboxylic acid** **Ethyl ether**  $\text{C}_6\text{H}_{11}(\text{CO}_2\text{Et})_{10}$ , i.e.

$\text{CH}_3(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2$ . So-called

$\text{CH}_3(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2$ , 'hexam' deca-carboxylic ether. A thick oil, obtained by treating

$\text{CH}_3(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{Cl}$  with  $\text{CH}_3(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{Na}$  (Bischoff, B. 21, 2115).

**HEXANE SULPHONIC ACID**  $\text{C}_6\text{H}_{13}\text{SO}_3\text{H}$ . Formed by oxidising hexyl mercaptan (from petroleum hexane) (Pelouze a. Cahours, A. 127, 192). Syrup.— $\text{BaA}'$  (at  $100^\circ$ ): scales.

**HEXECONTANE**  $\text{C}_{60}\text{H}_{122}$ . [102°]. Obtained by heating (10 pts. of) myricyl iodide (70–5°) with potassium (1 pt.) at  $135^\circ$ , the product being boiled successively with water, alcohol, petroleum-ether, and glacial acetic acid, and finally crystallised from benzene (Hell a. Hägele, B. 22, 503). V. sl. sol. hot alcohol and ether, sl. sol. petroleum-ether and  $\text{HOAc}$ , m. sol. chloroform and benzene. Partially decomposed by distillation. On distilling under reduced pressure there is formed a paraffin-like mass, v. sol. petroleum-ether, which extracts a hydrocarbon (70°).

**HEXENOIC ACID**  $\text{C}_6\text{H}_{10}\text{O}_2$ , i.e.  $\text{CH}_3\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ .  **$\alpha$ -Ethyl-crotonic acid**. Mol. w. 114. [41°]. (209°).

**Formation.**—1. From oxalic ether by treatment with  $\text{ZnEt}_2$  and decomposition of the resulting  $\text{CO}_2\text{Et.CEt}_2\text{OH}$  with  $\text{PCl}_5$ . By this means the ether is obtained, and is subsequently saponified (Frankland a. Duppa, C. J. 18, 133; Fittig a. Howe, A. 200, 21).—2. By heating  $\text{CO}_2\text{Et.CEt}_2\text{OEt}$  with  $\text{HCl}$  at  $150^\circ$  (Geuther, B. [2] 10, 34).—3. By treating  $\text{CO}_2\text{H.CEt}_2\text{OH}$  with  $\text{PCl}_5$ , and decomposing the distillate with water (Geuther).—4. By distilling oxyhexoic acid  $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  (Waldschmidt, A. 188, 245).

**Properties.**—Large four-sided prisms (after fusion); sl. sol. water, v. e. sol. alcohol and ether. Its aqueous solution reddens litmus but

its salts easily give up part of their acid when evaporated. Sublimes in the cold. Readily polymerised by heating or exposing to the air. Not affected by reducing agents.

**Reactions.**—1. **Potash-fusion** forms acetic and  $\pi$ -butyric acid (Petrie, B. 6, 1098).—2.  $\text{HBr}$  forms  $\text{C}_6\text{H}_{11}\text{BrO}$  [25°] which when boiled with water or alkalis gives amylenes and oxyhexoic acid [48°–52°] (Fittig a. Howe).—3. **Bromine** forms  $\text{C}_6\text{H}_8\text{Br}_2\text{O}_2$  [80–5°].—4. **Chromic acid mixture** forms  $\text{CO}_2$  and acetic acid (Chapman a. Smith, P. M. [4] 36, 290).—5.  $\text{KMnO}_4$  added to a very dilute solution of the K salt forms  $\text{CH}_3\text{CH}(\text{OH})\text{C}(\text{OH})\text{CO}_2\text{H}$  [96°] (Fittig, B. 21, 919).

**Salts.**— $\text{CuA}'_2$ : greenish-blue pp.— $\text{Cu}(\text{OH})\text{A}'$ : formed from the preceding by heating with alcohol.— $\text{PbA}'_2$ : crystalline pp., sl. sol. water.— $\text{AgA}'$ : scales (from hot water).

**Ethyl ether**  $\text{EtA}'$ . (165°). S.G. 15–920. Mobile oil, smelling of peppermint and of fungi (F. a. D.). Saponified by boiling alcoholic  $\text{KOH}$ .

Hexenoic acid  $\text{C}_6\text{H}_{10}\text{O}_2$ , i.e.

$\text{CH}_3\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  (?).  **$\gamma$ -Ethyl-crotonic acid**.

(c.  $126^\circ$  at 26 mm.). From tri-methyl-leucine  $\text{Pr.CH}_2\text{CH}(\text{NMe}_2\text{OH})\text{CO}_2\text{H}$  by heating at  $125^\circ$  (Körner a. Monozzi, G. 13, 354). Liquid. Combines with  $\text{HBr}$ . Its Cd salts form long prisms.

Hexenoic acid  $\text{C}_6\text{H}_{10}\text{O}_2$ , i.e.  $\text{CH}_3\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ .

**$\beta$ -Ethyl-methacrylic acid**. [24°]. (218° cor.).

S.G.  $\frac{22}{15}$  0.912. One of the products of the oxidation of the corresponding aldehyde (methyl-

ethyl-acrolein) (Lieben a. Zeisel, M. 4, 70; Solomina, J. R. 1887, 302). Monoclinic prisms;

$a:b:c = 1.41:1:1.385$ ;  $\beta = 104^\circ 38'$ . Volatile with steam;

sl. sol. water, v. e. sol. ether and benzene.

Combines with bromine, forming di-bromo-hexoic acid.

Reduced by zinc and  $\text{HBr}$  (or  $\text{HI}$ ) to methyl-propyl-acetic (hexoic) acid.

Its soluble salts give white pps. with salts of  $\text{Zn}$ ,  $\text{Ag}$ , and  $\text{Pb}$ , a blue pp. with  $\text{CuSO}_4$  and an oily pp. with  $\text{FeCl}_3$ .

$\text{CaA}'_2$ , 4aq: prisms or silky needles.— $\text{AgA}'$ : sparingly soluble needles or leaflets.

Hexenoic acid  $\text{C}_6\text{H}_{10}\text{O}_2$ , i.e.

$(\text{CH}_3)_2\text{C}(\text{CH}_2\text{CH}_2\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ .

**Pyroterebic acid**.

Formed, together with terebic acid and the lactone of oxy-isohexoic acid, by the dry distillation of terebic acid (Chautard, J. Ph. [3] 28, 192; Williams, B. 6, 1095; Mielck, A. 180, 52). If the process be conducted slowly the lactone is the chief product, if rapidly, pyroterebic acid is mainly produced.

The distillate is heated with baryta-water, and  $\text{CO}_2$  is passed in until the ppd.  $\text{BaCO}_3$  is redissolved; the lactone is then extracted with ether, and on evaporating the residue barium terebionate crystallises out.

The mother-liquor is treated with  $\text{H}_2\text{SO}_4$ , and pyroterebic acid distilled over with steam, and purified by means of its  $\text{Ca}$  salt. The yield is about 14 p.c. (Geisler, A. 208, 27).

**Properties.**—Liquid, not solidifying at  $-15^\circ$ ; sl. sol. water. On adding 3 or 4 vols. of water to the dry acid a homogeneous liquid is obtained but further addition of water causes separation into two layers, the upper one being the acid. The acid is not affected by boiling for some time with water.

**Reactions.**—1. Converted by prolonged heating at its boiling-point into the isomeric lactone of oxy-isohexoic acid. The same change occurs

when HBr is passed into the acid, probably through intermediate formation of the acid  $(\text{CH}_2)_6\text{OBr}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ .—2. Bromine forms a di-bromo-isohexenoic acid.

**Salts.**— $\text{CaA}'_2$  3aq; glistening prisms.— $\text{AgA}'$ : leaf-like crystals, sl. sol. water.

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ . Formed by oxidising hexenyl alcohol with chromic acid mixture (Destrem, *A. Ch.* [5] 27, 72). Liquid, volatile with steam. Split up by potash-fusion into acetic and butyric acids. Its salts are amorphous. Probably identical with the preceding acid.

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ , *i.e.*  
 $\text{CH}_3\cdot\text{CMe}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  or  
 $(\text{CH}_2)_5\cdot\text{C}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ . (203° uncor.). Formed

from the lactone of  $\gamma$ -oxy-isohexenoic acid by boiling with alcohol and NaOEt for 12 hours (H. Erdmann, *A.* 228, 183). Colourless liquid with pungent odour and acid taste. When boiled for a long time it partially changes to the isomeric lactone of  $\gamma$ -oxy-isohexenoic acid.— $\text{CaA}'_2$  2aq.— $\text{CaA}'_2$  3aq; trimetric crystals.— $\text{AgA}'$ .

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ , *i.e.*  $\text{Pr}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  (?). **Isoproperebic acid.** Formed, together with isosorbic acid, by the action of  $\text{CO}_2$  on crude  $\text{C}_4\text{H}_8\text{Na}$ , possibly through presence of  $\text{C}_2\text{H}_5\text{Na}$  as an impurity (Lagermark a. Eltekoff, *B.* [2] 23, 159; *J.* 11, 125). Liquid, sl. sol. water; heavier than water. Slightly volatile with steam. Combines with HBr. Bromine forms  $\text{C}_6\text{H}_{10}\text{Br}_2\text{O}_2$  [99°]. The silver salt dissolves in water.

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ , *i.e.*  $\text{Pr}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  (?). **Hydrosorbic acid.** (205° cor.); (208° i.v.). (Fittig, *A.* 200, 42). S.G. 1.2969. Formed by reducing sorbic acid with sodium amalgam (Fittig a. Barringer, *B.* 9, 1198; *A.* 161, 309). Liquid; on prolonged boiling it is decomposed, the boiling-point being raised. Combines with bromine. Combines with fuming  $\text{HBrAq}$  readily in the cold, forming liquid bromo-hexenoic acid (Stahl, *B.* 9, 120). Potash-fusion gives acetic and  $n$ -butyric acid. On warming with  $\text{H}_2\text{SO}_4$  it changes to the lactone of oxy-hexenoic acid. Its rate of etherification has been studied by Menschutkin (*B.* 13, 163).— $\text{CaA}'_2$  2aq [c. 125°]. S. (of  $\text{CaA}'_2$ ) 6:2 at 16°. Needles, more sol. cold than hot water.— $\text{BaA}'_2$  [above 265°]. Needles.— $\text{CuA}'_2$ ; green pp. [185°–190°].— $\text{AgA}'$ : pp. Sl. sol. cold water.

**Ethyl ether EtA'**. [167°].

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ . **Isohydrosorbic acid.** [–10°]. (209° i.v.). Formed, together with the lactone of oxy-hexenoic acid, by boiling bromo-hexenoic acid (the hydrobromide of hydrosorbic acid) with water (Hjelt, *B.* 15, 618; cf. Landsberg, *A.* 200, 51). Combines with HBr, forming the parent bromo-hexenoic acid.— $\text{CaA}'_2$  2aq; laminæ; more sol. hot than cold water.

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ . **Hexylenic acid.** [39°]. From tri-chloro-hexenoic acid, zinc, and  $\text{HClAq}$  (Zinner, *B.* 10, 1354). Long flat needles (from ether), or lozenge-shaped plates (from ligroin); nearly insol. water, v. sol. alcohol. Does not sublime in the cold.

**Hexenoic acid**  $\text{C}_6\text{H}_{10}\text{O}_2$ . (208°). Occurs in small quantity in croton oil (Schmidt a. Berendes, *A.* 191, 121).

**References.**—Bromo- and Chloro-hexenoic acids.

**HEXENOIC ALDEHYDE**  $\text{C}_6\text{H}_8\text{O}$  *i.e.*  $\text{Et}\cdot\text{CH}\cdot\text{CMe}\cdot\text{CHO}$ . **Methyl-ethyl-acrolein.** (137°

cor.). S.G. 0.86. Formed by heating proionic aldehyde at 100° with an equal volume of a solution of NaOAc (containing 21 p.c. NaOAc); on fractionally distilling the product the chief portion passes over at 135°–140° (Lieben a. Zeisel, *M.* 4, 10). Colourless liquid, with penetrating odour, insol. water. Gradually turns yellow on exposure to air. It forms a crystalline compound with  $\text{NaHSO}_4$ .

**Reactions.**—1.  $\text{HCl}$  forms unstable  $\text{C}_6\text{H}_8\text{ClO}$ . 2. Bromine forms  $\text{C}_6\text{H}_8\text{Br}_2\text{O}$ , a heavy oil which forms crystalline  $\text{C}_6\text{H}_8\text{Br}_2(\text{OH})\text{SO}_3\text{Na}$  3aq.—3. Iron filings and HOAc reduces it to a mixture of a hexyl alcohol  $\text{PrCHMe}\cdot\text{CH}_2\text{OH}$ , the corresponding aldehyde, and an alcohol  $\text{C}_6\text{H}_{12}\text{O}$ , which is readily converted into tri-oxy-hexane  $\text{Et}\cdot\text{CH}(\text{OH})\cdot\text{CMe}(\text{OH})\cdot\text{CH}_2\text{OH}$ .—4. Oxidation with chromic acid mixture, free oxygen, or moist silver oxide gives carbonic, formic, acetic, propionic, hexenoic (ethylmethacrylic), and di-oxy-hexenoic acids, together with methyl propyl ketone.—5. Ammonia unites with it, forming a solid product ( $\text{C}_6\text{H}_8\text{N}_2\text{O}$  or  $\text{C}_{12}\text{H}_{12}\text{N}_4$ ), which is converted at 140° into parvoline  $\text{C}_{11}\text{H}_{13}\text{N}$ , a homologue of pyridine (Waage, *M.* 4, 725). By heating the compound of hexenoic aldehyde with  $\text{NH}_3$  to 200° there is formed picoline, parvoline (196°), a base  $\text{C}_{11}\text{H}_{13}\text{N}$  (233°), and a base  $\text{C}_{11}\text{H}_{13}\text{N}$ , which is a mobile liquid, with pale-blue fluorescence. The parvoline gives, on oxidation, pyridine ( $\alpha\beta$ )-di-carboxylic acid (Hoppe, *M.* 9, 634).—6. Heated with aqueous  $\text{SO}_2$  for 4 hours at 80° there is formed, after neutralising with  $\text{BaCO}_3$ , a salt  $\text{C}_6\text{H}_8\text{O}(\text{SO}_3)_2\text{Ba}$  2aq, which is split up by heating with baryta-water into barium sulphite and hexenoic aldehyde. If the contents of the tube are boiled with water before neutralising there is obtained amorphous  $\text{C}_6\text{H}_{12}(\text{SO}_3)_2\text{Ba}$ . 7. If the aldehyde be left in contact with aqueous  $\text{SO}_2$  for some days and the product be saturated with  $\text{BaCO}_3$  and oxidised with bromine water, there is formed a salt of sulpho-hexenoic acid:  $\text{C}_6\text{H}_8\text{SO}_3\text{Ba}$  crystallising in hexagonal plates (Ludwig, *M.* 9, 658).

**Hexenoic aldehyde**  $\text{C}_6\text{H}_8\text{O}$ . (155°–138°). Formed, together with allyl chloride and di-allyl oxide by heating allyl alcohol with dilute (10 p.c.)  $\text{HClAq}$  at 100° for 20 hours (Solonina, *J.* 1887, 302). Oil. Absorbs oxygen eagerly from the air, producing hexenoic (ethylmethacrylic acid). Forms an oxim [49°] (194°). Probably identical with the preceding aldehyde.

**HEXENYL ALCOHOL**  $\text{C}_6\text{H}_{12}\text{O}$  *i.e.*  $\text{CH}_2\cdot\text{CH}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{OH}$ . **Di-methyl-allyl-carbinol.** (120° cor.). S.G. 0.8438;  $d_4^{20}$  0.8307.  $R_D$  49.84 (Kanonnikoff). H.C. 914,000 (Lougouine, *A. Ch.* [5] 23, 385).

**Preparation.**—By slowly pouring a mixture of acetone and allyl iodide on granulated zinc at 0° (M. a. A. Szytzeff, *A.* 185, 151, 175). The product is mixed with water and distilled. In the preparation of this body from allyl iodide, zinc, and acetone, a by-product of the formula  $\text{C}_6\text{H}_{12}\text{O}$  (c. 176°) occurs if the allyl iodide contains isopropyl iodide. Its specific refractive power,  $R_D = 72.27$ , indicating a double union of carbon atoms. It combines with bromine forming  $\text{C}_6\text{H}_{12}\text{Br}_2\text{O}$ . With  $\text{PCl}_5$  it forms  $\text{C}_6\text{H}_{12}\text{Cl}_2$  which boils about 180°, with partial decomposition. The same body is also formed by the action of isopropyl iodide and zinc on the pur

hexenyl alcohol (W. Dieff, *J. pr.* [2] 27, 364). A mixture of acetone (75 g.), allyl iodide (205 g.), and isobutyl iodide (230 g.), is converted by zinc into di-methyl-allyl-carbinol, but a small quantity (2 g.) of an alcohol  $C_6H_{12}O$  (c. 195°) is formed. These bodies appear to be di-methyl-allyl carbinol, in which an atom of hydrogen is displaced by isopropyl and by isobutyl respectively (E. Schatzky, *J. pr.* [2] 30, 216). The alcohol  $C_6H_{12}O$  is converted by Na and MeI into a methyl ether  $CMe_2(OMe).C_6H_{11}$  (169°-172° uncor.),  $R_D$  77.01, S.G.  $\frac{1}{4}$  8027, which is oxidised by  $KMnO_4$  to acetic, isobutyric, oxalic, and methoxy-valeric acids (Kononovitch, *V. pr.* [2] 30, 399).

**Properties.**—Liquid, smelling like camphor; al. sol. water, with which it forms a hydrate  $C_6H_{12}O \cdot aq$  (117°).

**Reactions.**—1. *Chromic acid mixture* oxidises it to formic acid,  $\beta$ -oxy-isovaleric acid, and acetone.  $KMnO_4$  acts in like manner (Schirokoff, *J. pr.* [2] 23, 205).—2. *Bromine* forms  $C_6H_{12}Br_2O$ . 3.  $HOCl$ , followed by displacement of Cl by OH, gives tri-oxy-hexane (hexyl-glycerin) (Reformatzky, *J. pr.* [2] 31, 318).—4. By heating the alcohol (1 vol.) with  $H_2SO_4$  (2 vols.) and water (1 vol.) for 3 days at 100°, and distilling the oily product, two hydrocarbons are got, viz.  $C_6H_{10}$  boiling below 100°, and  $C_{12}H_{22}$  boiling at 180°-200°. The latter is purified by shaking with  $P_2O_5$  and redistilling, and exhibits the following properties: (194°-199°). V.D. 80.3 ( $H=1$ ). S.G.  $\frac{15}{4}$  853;  $\frac{21}{4}$  839. C.E. (0°-21°) 00082.  $R_D$  89.34. It combines readily with bromine. With fuming  $HCl$  it appears to form a compound  $C_{12}H_{20}HCl$ . It is oxidised by chromic mixture to acetone, acetic acid, propionic acid and a fixed acid with the formula  $C_6H_{10}O_8$  or  $C_{10}H_{18}O_8$  (W. Nikolsky, A. A. Saytzeff, *J. pr.* [2] 27, 380). Its specific rotation is 5.22 more than that calculated from Brühl's numbers. This would indicate three C=C groups (Albitzky, *J. pr.* [2] 30, 214). The hydrocarbon  $C_6H_{10}$  is formed by removal of  $H_2O$  from the alcohol, so that it is either  $(CH_3)_2C:CH.CH_2CH_2$  or  $CH_3C \begin{smallmatrix} CH_3 \\ | \end{smallmatrix} CH:CH_2CH_2$ . The hydrocarbon  $C_{12}H_{22}$  is a polymeride of this.

**Acetyl derivative**  $C_6H_{11}OAc$ . (133° cor.). S.G.  $\frac{15}{4}$  9007;  $\frac{18.5}{4}$  8832.

**Secondary hexenyl alcohol**  
 $CH_2:CH.CH_2CH_2CH(OH).CH_3$ . *Di-allylhydrate*. *Allyl-isopropyl alcohol*. (139°). S.G.  $\frac{15}{4}$  842 (Crow);  $\frac{2}{4}$  861 (Wurtz).

**Preparation.**—1. Allyl-acetone (1 vol.) is mixed with ether (1 vol.), and put into a flask containing water (2 vols.). Small pieces of sodium are thrown into the flask, which is cooled meanwhile by standing in water. The ethereal solution is poured off, dried over  $CaCl_2$ , and distilled (J. K. Crow, *C. J.* 33, 53; cf. Kablukoff, *J. R.* 1887, 513).—2. From hydriodide of diallyl and  $Ag_2O$  (Wurtz, *A. Ch.* [4] 3, 172).

**Properties.**—Sl. sol. water, v. sol. alcohol and ether. Sweet taste, but rather pungent odour. Combines violently with bromine. Gives acetic acid on oxidation (Sorokin, *J. pr.* [2] 23, 20).

**Acetate**  $C_6H_{11}CH_2CH(OAc).CH_3$ . (148°) (Crow); (158° cor.) (Markownikoff, *J. R.* 13, 355). Formed from the alcohol by heating with  $Ac_2O$  in a flask with inverted condenser. Formed

also from di-allyl di-hydro-iodide and  $AgOAc$ . Liquid with pleasant refreshing odour.

**Dibromide**

$CH_2Br.CHBr.CH_2CH_2CH(OH).CH_3$ . Formed by adding bromine to a solution of the alcohol in  $CHCl_3$ . The chloroform is then distilled off *in vacuo*. It cannot be distilled.  $K_2CO_3$  converts it into an oil,  $C_6H_{11}Br(OH)_2$ ; volatile with steam.

**Hexenyl alcohol**  $C_6H_{12}O$  *i.e.*  
 $CH_2:CH.CH(CMe_2).OH$ . (110°-115°). From the chloride of crotonic acid and  $ZnMe_2$  (Pawłowsky, *B.* 5, 331).

**Hexenyl alcohol**  $C_6H_{12}O$  *i.e.*

$CH_2:CH_2.CH(CMe_2).CH(OH)_2$ . One of the products of the action of iron filings and  $HOAc$  on hexenoic aldehyde (methyl ethyl-acrolein). Forms a bromide  $C_6H_{11}Br_2O$ , which is converted by distillation with water into a tri-oxy-hexane (Lieben & Zeisel, *M.* 28).

**Hexenyl alcohol**  $C_6H_{12}O$ . (137°). S.G.  $\frac{12}{4}$  891, S. 10 at 10°. Formed by distilling calcium glycerin  $CaC_6H_{11}O_2$  (Destrem, *A. Ch.* [5] 27, 58). Liquid, smelling like peppermint and allyl alcohol. Not reduced by sodium-amalgam. Na and K form gelatinous  $C_6H_{11}ONa$  and  $C_6H_{11}OK$ . Chromic acid oxidises it to pyroterebic acid. Bromine forms  $C_6H_{11}Br_2O$  (252°-255°); S.G.  $\frac{15}{4}$  1.99.  $PCl_5$  gives  $C_6H_{11}Cl$  (71°).  $HBr$  forms  $C_6H_{11}Br$  (100°); S.G.  $\frac{12}{4}$  1.35. Chlorine forms  $C_6H_{11}Cl_2O$  (205°-210°); S.G.  $\frac{12}{4}$  1.4.  $PI_3$  forms  $C_6H_{11}I$  (131°); S.G.  $\frac{12}{4}$  1.92, whence  $K_2S$  forms  $(C_6H_{11})_2S$  (169°).

**Acetyl derivative**  $C_6H_{11}OAc$ . (145°).

**Benzoyl derivative**  $C_6H_{11}OBz$ . [105°]. (275°-280°). Yellow prisms.

**Reference.**—CHLORO-HEXENYL ALCOHOL.

**HEXENYL CHLORIDE**  $C_6H_{11}Cl$ . *Chlorohexylene*. (71°). From the corresponding alcohol (Destrem, *A. Ch.* [2] 27, 5). Light oil.

**Hexenyl chloride**

$CH_2:CH.CH_2CH_2CHCl.CH_3$ . (130°-140°). Formed, together with di-chloro-hexane, by heating di-allyl (hexinene) with fuming  $HCl$  (Wurtz).

**Hexenyl chloride**  $C_6H_{11}Cl$ . (122°). S.G.  $\frac{11}{4}$  9036. V.D. 4.02. Formed by the action of conc. alcoholic  $KOH$  on the di-chloro-hexane, which is a by-product in the action of  $HOCl$  on hexylene from mannite (Henry, *C. R.* 97, 260).  $H_2SO_4$  converts it into a ketone  $C_6H_{10}O$  (125°); S.G.  $\frac{11}{4}$  8343; V.D. 3.45.

**HEXENYL GLYCERIN** v. TRI-OXY-HEXANE.

**DI-HEXENYL OXIDE**  $(C_6H_{11})_2O$ . *Diallyl oxide*. (180°). A product of the action of  $Ag_2O$  on the mono- or di-hydroiodide of diallyl (Wurtz, *A. Ch.* [4] 3, 175).

**Di-hexenyl oxide**  $(C_6H_{11})_2O$ . (117°). From hexenyl iodide and  $HgO$ . Also from  $C_6H_{11}I$  and  $C_6H_{11}ONa$  (= HEXENYL ALCOHOL). Oil, heavier than water (Destrem, *A. Ch.* [5] 27, 58).

**DI-HEXENYL SULPHIDE**  $(C_6H_{11})_2S$ . (169°). From iodo-hexylene and  $K_2S$  (Destrem, *A. Ch.* [5] 27, 58). Heavy oil, of nauseating odour. Gives a maroon-red colouration with  $H_2SO_4$ .

**HEXIC ACID**  $C_6H_{10}O_2$ ? [126°]. An acid formed from propyl-aceto-acetic ether by successive treatment with bromine and alcoholic  $KOH$  (Demarçay, *C. R.* 88, 126; cf. Fittig, *B.* 16, 1839; Pawłoff, *B.* 16, 486). Large pearly plates (from hot water).

**Isohexic acid**  $C_8H_{16}O_2$ ? [124°]. Formed in like manner from isopropyl-aceto-acetic ether. Prisms (from ether).

**HEXINENE**  $C_8H_{16}$ , *i.e.*  $Pr.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_3$ . *Butyl-acetylene*. (70°). Formed by the action of metallic sodium on methyl propyl acetylene at 160°, and decomposition of the sodium compound with water (Faworsky, *J. pr.* [2] 37, 428). Gives pps. with ammoniacal copper and silver solutions. Yields on treating the sodium compound with  $CO_2$  a carboxylic acid.

**Hexinene**  $Ma_2C_6CH_2$ . (39°). Formed by the action of alcoholic potash at 140° for 12 hours on di-chloro-tetra-methyl-ethane (Faworsky, *J. pr.* [2] 37, 393). Forms pps. with ammoniacal cuprous and silver solutions. Is not altered by heating with alcoholic potash to 200°.

**Hexinene**  $C_8H_{16}$ , *i.e.*  $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_3$ . This compound has been described as **DI-ALLYL** (*q.v.*). When heated with bromine it gives a crystalline mass [46°]. This is a mixture of two substances, [65°] and [56°], both having the formula  $C_8H_{16}Br_2$ . From this it appears that the di-allyl obtained by the action of Na on  $C_6H_5I$  is a mixture of two isomeric bodies, probably  $CH_2=CH.CH_2.CH_2.CH_2=CH_2$  and  $CH_3.CH_2.CH_2.CH_2.CH_2=CH_2$  (dipropenyl) (Sabaneff, *Bl.* [2] 45, 182). When diallyl is diluted with (1 vol.) paraffin oil and treated with  $H_2SO_4$ , the lower layer separated and distilled with water yields 'hexylene oxide,' a liquid  $C_8H_{16}O$ , smelling like menthol (93°). Oxidation of this  $C_8H_{16}O$  gives  $HOAc$  and  $CO_2$ ; sodium-amalgam has no action;  $HI$  at 100° gives  $\beta$ -hexyl iodide (166°) (Jewell, *Bl.* [2] 15, 233). Another method of hydration is to add the diallyl drop by drop to well cooled  $H_2SO_4$ . The acid is diluted with ice, neutralised, and distilled, when hexylene oxide passes over at 92°-95°. Some of the salt of the undecomposed sulphuric acid remains behind in the flask. The Ba and Ca salts can be obtained in this way (Béhal, *Bl.* [2] 43, 43).

**Hexinene**  $C_8H_{16}$ , (c. 83°). S.G. 1.3-1.71. V.D. 2-84 (calc. 2-79). Formed from petroleum hexane by bromination, followed by treatment of the resulting hexenyl bromide with alcoholic KOH at 155° (Caventou, *C. R.* 59, 449; Reboul a. Truchot, *C. R.* 65, 73). Forms a liquid dibromide and a crystalline tetrabromide.

**Hexinene**  $CH_3.CH_2.CH_2.CCl.CH_2.CCl.CH_2.CCl_3$ ? (80°-83°). S.G. § 7494; ¶ 7377. Formed by the action of alcoholic KOH on the hexenyl bromide derived from mannite *via* di-bromo-hexane (Hecht, *B.* 11, 1050). Does not ppt. ammoniacal silver or cuprous solutions. Oxidised by chromic acid mixture to acetic *n*-butyric acids.

**Hexinene**  $(CH_3)_2CCl.CH_2.CH_2.CCl_3$ ? (80°). From  $(CH_3)_2CCl.CH_2.CH_2.CCl_3$  and alcoholic KOH (M. a. A. Saytzeff, *A.* 185, 157; *v.* **HEXENYL ALCOHOL**).

**Hexinene**  $C_8H_{16}$ , (c. 80°). In coal tar (Schorlemmer, *A.* 139, 250). Forms  $C_8H_{16}Br_2$  [112°].

**Hexylene**  $C_8H_{16}$ , (70°-73°). V.D. 2-97. Obtained, with other products, by passing the vapour of heptinene through an iron tube heated to incipient redness (Renard, *C. R.* 104, 574). Rapidly absorbs oxygen. Does not ppt. ammoniacal  $AgNO_3$  or  $Cu_2Cl_2$ . Bromine forms un-

stable, oily  $C_8H_{16}Br_2$ . Conc.  $H_2SO_4$  polymerises it, forming  $C_{12}H_{22}$  (210°-215°).

*References.*—**DI-BROMO-** and **TETRA-CHLORO-HEXINENE**.

**HEXINENE GLYCOL** *v.* **DI-OXY-HEXINENE**.

**HEXINENE DIOXIDE**  $C_8H_{16}O_2$ , *i.e.*

$CH_3.CH_2.CH_2.CH_2.CCl.CH_2.CCl_3$ , (182°). Formed

by acting with KOH on the dichlorhydrin prepared by treating diallyl with hypochlorous acid (Przybytek, *Bl.* [2] 43, 110). Colourless mobile liquid. Heated with water it forms  $C_8H_{16}(OH)_2$  sol. alcohol, water, insol. ether. Treated with HCl a dichlorhydrin is formed.

**HEXINOIC ACID**  $C_8H_{16}O_2$ , *i.e.*  $Pr.CCl.CO.OH$ . [27°]. (125°) at 20 mm. Formed by the action of  $CO_2$  on the sodium compound of propyl acetylene suspended in ether (Faworsky, *J. pr.* [2] 37, 419). Feathery crystals. Sol. water, *v.* sol. alcohol, ether, and petroleum ether. Deliquesces in the air. Decomposes on heating or keeping into  $CO_2$  and propyl-acetylene. Its silver salt at once decomposes in the same way.

*Salts.*— $(C_8H_{16}O_2)_2Ba$  3aq. *V.* sol. water.— $A_2Cu$  2aq. Blue plates, *v.* sol. water.

**Hexinoic acid**  $C_8H_{16}O_2$ , [93°-96°]. From pyroterebic acid, by successive treatment with bromine and alcoholic KOH (Mielck, *A.* 180, 56). Crystalline mass; *m.* sol. water. Volatile with steam.— $BaA_2$ : amorphous.

**Hexinoic acid** *v.* **SORBIC ACID**.

**Hexinoic acid**  $C_8H_{16}O_2$ , *i.e.*

$(CH_3)_2CH.CCl.CO.OH$ . *Iso-sorbic acid*. From  $Pr.CClNa$  and  $CO_2$  (Lagermark a. Eltekoff, *J. R.* 11, 125). Liquid. Combines with HBr, forming  $C_8H_{16}Br_2O_2$ .

**Hexinoic acid**  $Pr.CCl.CO.OH$ . *Isopropyl-acetylene carboxylic acid*. [38°]. (107° at 20 mm.). From di-methyl-allylene sodium, and  $CO_2$  (Faworsky, *J. R.* 1887, 553). Should be identical with the preceding.

**HEXINYL ALCOHOL**  $C_8H_{18}O$ , *i.e.*  $C_8H_{17}OH$  (140°). A by-product of the action of glycerin on zinc-dust (Claus, *B.* 18, 2931).° Forms  $C_8H_{17}I$  (133°).

*Acetyl derivative*  $C_8H_{17}OAc$ . (124°).

**HEXINYL CHLORIDE**  $C_8H_{17}Cl$ . *Chloro-diallyl*. (150°). S.G. 1.3-1.9197. V.D. 4-15 (calc. 4-02). A product of the action of  $PCl_5$  upon allyl-acetone (Henry, *C. R.* 87, 171). Oil; combines with bromine, forming oily  $C_8H_{17}ClBr_2$ . Alcoholic KOH at 100° forms hexonene (diallylene). This hexinyl chloride is perhaps a mixture of the chloride  $C_8H_{17}Cl$ ,  $CCl:CH_2$ , with  $C_8H_{17}Cl.CCl:CH_2$ .

**Hexinyl chloride**  $C_8H_{17}Cl$ . (130°). From methyl oxide, by treatment with  $PCl_5$  and distillation of the resulting  $C_8H_{17}Cl_2$  with lime (Baeyer, *A.* 142, 298).

**HEXITAMALIC ACID** *v.* **OXY-HEPTYL-SUCCINIC ACID**.

**n-HEXOIC ACID**  $C_6H_{12}O_2$ , *i.e.*

$CH_3.CH_2.CH_2.CH_2.CCl_2.CO_2H$ . *n-Caproic acid*. Mol. w. 116. [-1-6°] (Fittig, *A.* 200, 48). (205°). S.G. § 9446 (Zander, *A.* 224, 67); § 9458 (Gartenmeister, *A.* 233, 277); ¶ 9287 (Brühl). C.E. (0°-10°) 0.00095 (Z.). S.V. 152-6 (Z.).  $\mu_2$  1.4190.  $R_{D_20}$  50-56 (B.). H.C. 880,209 (Lougouine, *A. Ch.*

[5] 25, 140). *Heat of neutralisation*: Gal a. Werner, *Bl.* [2] 46, 802.

*Occurrence*.—Among the products of the butyric fermentation of sugar (Grillone, *A.* 165, 127; cf. Sticht, *Z.* 1868, 220; Linnemann, *A.* 160, 225; Lieben, *A.* 170, 89).

*Formation*.—1. By the oxidation of *n*-hexyl alcohol (Zincke, *A.* Franchimont, *A.* 163, 199).—2. By the action of boiling alcoholic KOH on its nitrile (*n*-amyl cyanide) (Lieben, *A.* Rossi, *G.* 1, 814; 3, 27; *A.* 159, 75; 165, 118).—3. Together with other fatty acids by the oxidation of proteids.—4. From *n*-butyl-aceto-acetic ether and alcoholic KOH (Gartenmeister, *A.* 233, 277).

*Preparation*.—By fractionally distilling crude fermentation butyric acid, and shaking the portion boiling above 180° with 6 volumes of water.

*Properties*.—Oil, with faint unpleasant odour.

*Reactions*.—1. Oxidised by nitric acid to acetic and succinic acids (Erlennmeyer, Sigel, *B.* 7, 696; *A.* 180, 215).—2. Magnesium caproate in solution subjected to an alternating electric current produces butyric, valeric, oxycaproic, oxalic, succinic, glutaric, and adipic acids (Drechsel, *J. pr.* [2] 34, 135).

*Salts*.—CaA', aq. S. 2.6 at 18° (Kottal, *A.* 170, 95); 4.6 (Grillone); 2.73 at -7° (Keppeich, *M.* 9, 589).—BaA', S. 9.3 at 18.5° (Lieben, *A.* Rossi); 9.1 at 22° (Grillone); 9.47 at 5° (Keppeich).—BaA', 2aq. S. (of BaA') 12.5 at 10.5° (Lieben, *A.* Jancock, *A.* 187, 128).—BaA', 3aq. S. (of BaA') 12.9 at 23° (K.).—SrA', 3aq. laminae. S. 9.7 at 24° (K.).—ZnA', aq. S. 1 at 24° (K.).—CdA', 2aq. S. 1 at 24° (K.).—CuA', insol. ether, sol. alcohol. —AgA', pp. (Franchimont, *A.* Zincke, *A.* 163, 200). S. 0.77 at 0° (Keppeich).

*Methyl ether* MeA' (150°). S.G.  $\frac{1}{4}$  0.939. C.E. (0°-10°) 0.0105. S.V. 172.2 (Gartenmeister).

*Ethyl ether* EtA'. Mol. w. 144. (166.6°) (G.). S.G.  $\frac{1}{4}$  0.888. C.E. (0°-10°) 0.0103. S.V. 197.7.

*Propyl ether* PrA' (186°). S.G.  $\frac{1}{4}$  0.844. C.E. (0°-10°) 0.0101. S.V. 222.2.

*Butyl ether* Pr.CH.A' (204°). S.G.  $\frac{1}{4}$  0.824. C.E. (0°-10°) 0.0099. S.V. 246.0.

*n-Hexyl ether* C<sub>6</sub>H<sub>13</sub>A' (246° cor.). S.G.  $\frac{1}{4}$  0.865 (Franchimont, *A.* Zincke, *A.* 163, 197).

*Heptyl ether* C<sub>7</sub>H<sub>15</sub>A' (259°). S.G.  $\frac{1}{4}$  0.8769. C.E. (0°-10°) 0.0088. S.V. 323.9.

*n-Octylether* C<sub>8</sub>H<sub>17</sub>A' (275°). S.G.  $\frac{1}{4}$  0.8748. C.E. (0°-10°) 0.0088. S.V. 349.6 (Gartenmeister). Occurs in oil of *Heracleum* (Zincke, *A.* 163, 18).

*Chloride* C<sub>6</sub>H<sub>11</sub>OCl. (c. 138°) (Béchamp, *A.* 130, 364).

*Anhydride* (C<sub>6</sub>H<sub>11</sub>O)<sub>2</sub>O. Liquid (Chiozza, *A.* 86, 259).

*Acetyl-hexoic anhydride* C<sub>6</sub>H<sub>11</sub>O.OAc. (165°-175°). Liquid, lighter than water. Formed by heating hexoic acid with Ac<sub>2</sub>O (Autenrieth, *B.* 20, 3187).

*Amide* [100°]. (255°) (Henry, *B.* 2, 490). Plates. Sol. alcohol and hot water. Prepared by heating ammonium hexoate at 280° under pressure; the yield is 70 p.c. (Hofmann, *B.* 15, 983; 17, 1411).

*Anilide* O.H<sub>11</sub>.CONHPh. [95°]. Formed by heating with aniline (Kelbe, *B.* 16, 1200). Needles, v. sol. alcohol and ether.

*Phenyl hydrazide* C<sub>6</sub>H<sub>11</sub>.CO.NH.NHPh. [117°].

*Nitrile* C<sub>6</sub>H<sub>11</sub>CN. *n-Amyl cyanide*. Mol. w. 97. (154°). S.V. 141.1 (R. Schiff, *B.* 19, 568). Formed, together with hexylamine, by allowing a mixture of the amide of heptoic acid (1 mol.) and bromine (3 mols.) to run into a 10 p.c. solution of NaOH (Hofmann, *B.* 17, 1410).

*Isohexoic acid* C<sub>6</sub>H<sub>12</sub>O<sub>2</sub>, i.e. Pr.CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H. *Isocaproic acid*. *Isobutyl-acetic acid*. (200° i.V.). S.G.  $\frac{1}{4}$  0.925. *Heat of neutralisation*: Gal a. Werner, *Bl.* [2] 46, 802).

*Occurrence*.—As glyceryl ether in butter (Chevreul, *Recherches sur les corps gras*), in cheese, and in cocoa-nut oil (Fehling, *A.* 53, 406). Occurs in the free state, together with butyric and valeric acids in the flowers of *Satyrion hircinum*, which have an odour of bugs (Chautard, *Bl.* [2] 2, 56); and, together with several of its lower homologues, in the sarcocarp of *Ginkgo biloba* (Béchamp, *A.* 130, 364). Found by C. Kraut (*A.* 103, 29) in the water of a brook running out of a peaty soil. Formed also by the fermentation of wheat bran (Freund, *J. pr.* [2] 3, 224).

*Formation*.—1. By saponifying its nitrile (isoamyl cyanide), which is obtained from isoamyl iodide by boiling with alcohol and calcined K<sub>2</sub>FeCy<sub>4</sub> (Frankland, *A.* Kolbe, *A.* 65, 303; Wurtz, *A.* 105, 295).—2. By the action of CO<sub>2</sub> on sodium isoamyl (produced by treating ZnEt<sub>2</sub> with sodium) (Wanklyn, *A.* Schenk, *C.* J. 21, 81).—3. By the oxidation of proteids, fats, and oils, hexoic acid is often formed, but in most cases it has not been determined whether it is *n*- or iso-hexoic acid (Redtenbacher, *A.* 59, 41; Schneider, *A.* 70, 112; Arzbacher, *A.* 73, 203; Guckelberger, *A.* 64, 70).—4. From  $\gamma$ -oxy-isohexoic acid by heating with HI and red phosphorus (Mielek, *A.* 180, 45).—5. By decomposing isobutyl-aceto-acetic ether with baryta (Rohn, *A.* 190, 316).—6. Either *n*- or iso-hexoic acid occurs to the extent of 3 p.c. among the acids produced by the fermentation of the perspiration of sheep (yolk).—7. From leucine and nitrous acid.—8. One of the products of the action of zinc isoamyl on oxalic ether (Frankland, *A.* Duppa, *A.* 142, 17).

*Properties*.—Liquid, with rancid smell. Not solidified by cooling to -18°. When its potassium salt in aqueous solution is decomposed by an electric current decane is produced (Brazier, *A.* Grossleth, *A.* 75, 249).

*Reaction*.—Oxidised by KMnO<sub>4</sub> to  $\gamma$ -oxy-isohexoic acid (CH<sub>3</sub>)<sub>2</sub>C(OH).CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H which splits off water, giving the lactone

*Salts*.—CaA', 3aq. S. (of CaA') 12.7 at 18.5° (Lieben, *A.* Rossi, *A.* 165, 124); 5.8 at 21° (Mielek); 9.9 at 19° (Rohn).—BaA', aq. S. (of BaA') 21 at 22° (Mielek).—BaA', 2aq. S. 53 at 18.5° (L. a. R.); 25 at 14° (Rohn).

*Methyl ether* MeA' (150°). S.G.  $\frac{1}{4}$  0.898 (Fehling, *A.* 53, 440).

*Ethyl ether* EtA' (161° cor.). S.G.  $\frac{1}{4}$  0.887; 0.8705 (L. a. R.).

*Isoamyl ether* C<sub>6</sub>H<sub>11</sub>A' (215°-220°) (Frankland, *A.* Duppa, *A.* 142, 18).

*Amide* Pr.CH<sub>2</sub>.CH<sub>2</sub>.CONH<sub>2</sub>. [120°]. Prepared by heating ammonium isocaproate at 230°

under pressure; the yield is 63 p.c. of the theoretical (Hofmann, *B.* 15, 983; 17, 1411).

**Nitrile**  $\text{Pr} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CN}$ . *Isoamyl cyanide*. (155°) (Wurtz, *A.* 105, 296). S.G.  $\frac{20}{806}$ . V.D. 3.34. Formed by heating isoamyl oxalate, chloride, or iodide with KCy (calcined  $\text{K}_2\text{FeCy}_4$ ) (Balard, *A. Ch.* [3] 12, 294; Frankland & Kolbe, *A.* 65, 288; Brazier & Gossleth, *A.* 75, 251; Medlock, *A.* 69, 220; Wurtz, *A.* 105, 296). So prepared it is dextrorotatory;  $[\alpha]_D = +1.59$ , and is therefore impure. It forms the following compounds:  $(\text{C}_6\text{H}_5)_3\text{N} \cdot \text{TiCl}_4$ . —  $(\text{C}_6\text{H}_5)_3\text{N} \cdot \text{SnCl}_4$ . —  $\text{C}_6\text{H}_5\text{N} \cdot \text{SnCl}_4$ .

**Hexoic acid**  $\text{C}_6\text{H}_{12}\text{O}_2$  i.e.  $\text{CHPrMe} \cdot \text{CO}_2\text{H}$ . *Methyl-propyl-acetic acid*. (194° cor.). S.G.  $\frac{25}{9231}$ ;  $\frac{19}{9279}$  (Liebemann & Scheibler, *B.* 16, 1823);  $\frac{18}{9286}$  (Liebemann & Kiemann, *B.* 17, 918). C.E. -00075.

**Formation**.—1. From amylene by combination with  $\text{HI}$ , treatment of the product with  $\text{KCy}$  at  $115^\circ$ , and saponification of the product (A. Saytzeff, *B.* 11, 511; *A.* 193, 349).—2. By oxidising  $\text{Pr} \cdot \text{CHMe} \cdot \text{CH}_2\text{OH}$  with chromic acid mixture (Lieben & Zeisel, *M.* 4, 37).—3. By reducing  $\text{Et} \cdot \text{CH} \cdot \text{CMe} \cdot \text{CO}_2\text{H}$  with  $\text{HI}$  (L. a. Z.).—4. By reduction of the lactone of  $\gamma$ -oxy- $\alpha$ -methyl-valeric acid (caprolactone) by heating with  $\text{HI}$  and red phosphorus at  $200^\circ$  (L. a. S.).—5. By the action of  $n$ -propyl iodide on sodium methyl-aceto-acetic ether and saponification of the product (L. a. K.; E. J. Jones, *A.* 226, 294).—6. From isosaccharin by reduction with  $\text{HI}$  and  $\text{P}$  (Kiliani, *B.* 18, 632).—7. In oil of resin, obtained by the dry distillation of colophony (Kelbe & Warth, *J.* 15, 308).

**Properties**.—Inactive liquid, sl. sol. water. Weak acid.  $\text{FeCl}_3$  gives, in a solution of the ammonium salt, a flesh-coloured pp. soluble in excess of the reagent (S.).

**Salts**.— $\text{CaA}'$ . Prisms (from alcohol) (S.; L. a. Z. obtained  $\text{CaA}' \cdot \text{aq}$ ).— $\text{CaA}' \cdot \text{aq}$ : small needles (from a solution saturated at  $50^\circ$ ) (K. a. W.).— $\text{CaA}'_2 \cdot 2\frac{1}{2}\text{aq}$ : long needles. S.  $11.8$  at  $17^\circ$ ;  $7.6$  at  $100^\circ$ .— $\text{CaA}'_2 \cdot 3\text{aq}$  (L. a. Z.).— $\text{CaA}'_2 \cdot 4\text{aq}$  (L. a. Z.).— $\text{CaA}'_2 \cdot 5\text{aq}$  (L. a. Z.).— $\text{CaA}'_2 \cdot 8\text{aq}$ : silky needles (Kiliani). S. (of  $\text{CaA}'_2$ ) 32 at  $18.5^\circ$  (A. Saytzeff, *J. pr.* [2] 23, 293).— $\text{BaA}'$ : gummy; v. sol. water (S.).— $\text{ZnA}'_2$ : more sol. cold, than hot, water (S.).— $\text{CuA}'_2$ : light green pp.— $\text{AgA}'$ : slender needles. S.  $.47$  at  $20^\circ$ ;  $.9$  at  $100^\circ$  (S.).

**Ethyl ether EtA'**. (153° i.v.). S.G.  $\frac{20}{8816}$ ;  $\frac{19}{8670}$  (A. Saytzeff, *A.* 193, 352).

**Hexyl ether C<sub>6</sub>H<sub>11</sub>A'**. (224° cor.). Formed in the oxidation of  $\text{OMePrH} \cdot \text{CH}_2\text{OH}$  by chromic acid mixture (L. a. Z.).

**Amide C<sub>6</sub>H<sub>11</sub>CONH<sub>2</sub>**. [95°]. Needles (K. a. W.).— $(\text{C}_6\text{H}_5)_3\text{N} \cdot \text{CONH} \cdot \text{Hg}$ . [c.  $158^\circ$ ]. Needles.

**Hexoic acid**  $\text{C}_6\text{H}_{12}\text{O}_2$  i.e.  $\text{CHPrMe} \cdot \text{CO}_2\text{H}$ . *Methyl-isopropyl acetic acid*. (190°). S.G.  $\frac{15}{928}$ .

**Formation**.—1. From  $\text{CHPrMeI}$  vid  $\text{HPrMeCN}$  (Markownikoff, *Z.* 1866, 502).—2. From methyl-isopropyl-aceto-acetic ether, obtained by treating aceto-acetic ether successively with  $\text{NaOEt}$  and  $\text{PrI}$  followed by  $\text{MeI}$ ; or with  $\text{MeI}$  followed by  $\text{PrI}$ . Neither method gives a good yield (Van Romburgh, *R. T. C.* 5, 228).—4. From malonic ether by like processes (R.).

**Properties**.—Liquid, smelling like its isomerides.

**Salts**.— $\text{CaA}'$ . Less sol. hot, than cold, water. S. 20 at  $15^\circ$ . Slender needles (from alcohol).— $\text{AgA}'$ : needles (from water).

**Amide**  $\text{C}_6\text{H}_{11}\text{CONH}_2$ . [129°]. Sol. water, alcohol, ether, and benzene. Easily sublimed (R.).

**Hexoic acid**  $\text{C}_6\text{H}_{12}\text{O}_2$  i.e.  $\text{CHMe} \cdot \text{CO}_2\text{H}$ . *Dimethyl-ethyl-acetic acid*. [ $-14^\circ$ ]. (186°). Obtained from the corresponding iodide  $\text{CHMe} \cdot \text{CH}_2\text{I}$  by heating with potassio-mercuric cyanide, fractionally distilling the resulting nitrile, and then heating it with fuming  $\text{HCl}$  for 6 days at  $100^\circ$ , and then for 2 days at  $120^\circ$  (Wischegradsky, *B.* 7, 730; *A.* 174, 56; 178, 103). Formed also by reducing methyl ethyl ketone with sodium amalgam and oxidising the resulting pinacol  $\text{C}_6\text{H}_{14}\text{O}$  with  $\text{CrO}_3$  (Lavrionovitch, *A.* 185, 120).

**Salts**.— $\text{BaA}'_2$ : large transparent plates (from water); v. sol. water.— $\text{ZnA}'_2$ : white pp.— $\text{AgA}'$ : slender needles (from hot water).

**Chloride**  $\text{CMe} \cdot \text{Et} \cdot \text{COCl}$ . (132°).

**Nitrile**  $\text{CMe} \cdot \text{Et} \cdot \text{CN}$ . (130°).

**Hexoic acid**  $\text{C}_6\text{H}_{12}\text{O}_2$  i.e.  $\text{CH}_2\text{H} \cdot \text{CO}_2\text{H}$ . *Diethyl-acetic acid*. (190° i.v.) (Saytzeff). (191°) (Burton, *Am.* 8, 393); (196°) (Schnapp, *A.* 201, 70). S.G.  $\frac{20}{936}$ ;  $\frac{19}{920}$  (Saytzeff);  $\frac{18}{945}$  (Schnapp).

**Formation**.—1. From oxy-hexoic ether (diethyl-oxalic ether)  $\text{CH}_2\text{H} \cdot \text{CO} \cdot \text{Et}$  by treatment with  $\text{PCl}_5$  which gives  $\text{CH}_2\text{H} \cdot \text{CO} \cdot \text{Et}$ , which is then reduced by sodium amalgam (Markownikoff, *B.* 6, 1175). The same chloro-hexoic ether is resolved by distillation into  $\text{HCl}$  and hexenoic ether, which may be reduced in like manner by sodium-amalgam.—2. From di-ethyl-aceto-acetic ether (Frankland & Duppa, *A.* 138, 218).—3. By passing  $\text{CO}$  over a mixture of  $\text{NaOEt}$  and  $\text{NaOAc}$  heated to  $205^\circ$  (Fröhlich, *A.* 202, 308).—4. Together with aldehyde, by distilling  $\beta$ -oxy-di-ethyl-butyric acid  $\text{CH}_3\text{CH}(\text{OH}) \cdot \text{CH}_2\text{CO}_2\text{H}$  (Schnapp, *A.* 201, 70), or by treating the same acid with  $\text{PCl}_5$  followed by water (Burton). Also from the same acid and  $\text{HI}$  (B.).—5. From  $\text{CH}_2\text{H} \cdot \text{I}$  vid the cyanide (A. Saytzeff, *A.* 193, 349).—6. From di-ethyl-malonic ether (Conrad, *A.* 204, 141).—7. From ethyl-crotonic acid  $\text{CH}_3\text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$  by combining with  $\text{HBr}$  and reducing the resulting bromo-hexoic acid (Howe & Fittig, *A.* 200, 24; A. Saytzeff, *J. pr.* [2] 23, 288).

**Properties**.—Liquid; not solidified at  $\approx 15^\circ$ .

**Salts**.— $\text{CaA}'$ . S. 25 at  $23^\circ$ . Gummy (from water) or twin-crystals (from alcohol).— $\text{CaA}' \cdot \text{aq}$ : laminae. S. (of  $\text{CaA}'_2$ ) 33 at  $18.5^\circ$  (H. a. F.); 30 at  $-7^\circ$  (Keppich, *M.* 9, 589). On evaporating the solution a thin crust forms which dissolves again on cooling. Crystals may be obtained by stirring during evaporation.— $\text{BaA}'_2$ : gummy.— $\text{ZnA}'_2$ : less sol. hot than cold water.— $\text{AgA}'$ : S.  $.4$  at  $-7^\circ$  (Keppich);  $.5$  at  $20^\circ$ ;  $.75$  at  $100^\circ$ .

**Ethyl ether EtA'**. (151°). S.G.  $\frac{20}{883}$ ;  $\frac{19}{869}$  (Saytzeff).

**Hexoic acid**  $\text{C}_6\text{H}_{12}\text{O}_2$  i.e.  $\text{CHMe} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ .  *$\beta$ -Methyl- $\beta$ -ethyl-propionic acid*. (c.  $197^\circ$ ). S.G.  $\frac{15}{930}$ .  $[\alpha]_D = +8.92^\circ$ . Formed by oxidising active hexyl alcohol by  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  (Van Romburgh, *R. T. C.* 5, 222).

**Salts**.— $\text{CaA}'_2$ : tufts of small needles (from water).— $\text{AgA}'$ : needles (from hot solutions).

**Hexyl ether C<sub>6</sub>H<sub>11</sub>A'**. (238°). S.G.  $\frac{15}{930}$ .

·867.  $[\alpha]_D = 12.86^\circ$ . Formed in the oxidation of the alcohol.

*Amide*  $C_6H_{13}CONH_2$ . [124°].

*References*.—AMIDO-, BROMO-, and CHLORO-HEXOIC ACIDS.

*n*-HEXOIC ALDEHYDE  $C_6H_{12}O$  *i.e.*  $Pr.CH_2.CH_2.CHO$ . *n*-Caproic aldehyde. Mol. w. 100. (128° cor.). S.G.  $d_{20}^{20} = 0.850$ ;  $d_{20}^{20} = 0.831$ . Formed by distilling calcium caproate (10 pts.) with calcium formate (7½ pts.) (Lieben a. Janacek, A. 187, 130; C. J. 32, 879). Limpid liquid, smelling like aldehyde. Forms a crystalline compound with  $NaHSO_3$ . Is readily oxidised and readily polymerised.

Hexoic aldehyde  $Pr.CH_2.CH_2.CHO$ . *Isocaproic aldehyde*. (121°). Formed by distilling sodium formate with sodium isohexanoate (Rossi, A. 133, 178). Liquid with pungent odour, sl. sol. water, miscible with alcohol and ether. Reduces ammoniacal  $AgNO_3$ . Gives on oxidation isohexoic (isobutyl-acetic) acid. Reduced by sodium-amalgam to hexyl alcohol (150°). Combines with  $NaHSO_3$ .

Hexoic aldehyde  $C_6H_{12}O$  *i.e.*  $Pr.CHMe.CHO$ . (116° cor.). From  $Et.CH:CMc.CHO$ , iron, and dilute  $HNO_3$  by standing in the cold for a month (Lieben a. Zeisel, M. 4, 23). Combines with  $NaHSO_3$ . Gives  $Pr.CHMe.CO_2H$  on oxidation.

*Reference*.—TRI-CHLORO- and DI-BROMO-HEXOIC ALDEHYDE.

HEXONENE  $C_6H_{12}$ . (80°–85°). S.G. ·80. Among the products deposited on compressing the gas obtained by heating oils (Courbe, J. 17, 18, 165). The same hydrocarbon (85.5°) occurs in petroleum from Amiano (Dumas, A. 6, 267).

Isomeride: DIALLYLENE (*q.v.*). V. also BROMO-HEXONENE.

HEXONITRILE *v.* Nitrile of HEXOIC ACID.

HEXONYL BROMIDE  $C_6H_{13}Br$ . *Bromo-diallylene*. (150°). From di-bromo-diallyl and  $KOH$  (Henry, B. 14, 400). Liquid, heavier than water. Combines with bromine. Ppts. ammoniacal  $AgNO_3$  and  $Cu_2Cl_2$ .

HEXUNENE  $C_6H_{12}$ . (64°). (130°). V.D. 2·81. Formed by distilling cuprous allylide with an alkaline solution of  $K_2FeCy_4$  (Griner, C. R. 105, 283). In presence of  $CS_2$ , it combines with bromine forming crystalline  $C_6H_8Br_2$  [14°]. It does not ppt. ammoniacal cuprous chloride.

Isomerides. BENZENE and DIPROPARGYL.

DI-HEXYL *v.* DODECANE.

HEXYL ACETATE *v.* Acetyl derivative of HEXYL ALCOHOL.

HEXYL ACETYLENE *v.* OCTINENE.

*n*-HEXYL ALCOHOL  $C_6H_{14}O$  *i.e.*  $Pr.CH_2.CH_2.CH_2.OH$ . Mol. w. 102. (157° cor.). S.G.  $d_{20}^{20} = 0.832$ . C.E. (0°–10°) ·00087. S.V. 146·2 (Zander, A. 224, 82). Occurs in fusel oil from brandy (Paget, A. 88, 326) to the amount of 6 p.c. (Ordonneau, C. R. 102, 219). *n*-Hexyl acetate and butyrate occur in the essential oil of *Heraclium* (Franchimont a. Zincke, B. 4, 822; A. 163, 198; Möslinger, A. 185, 41). Perhaps the hexyl alcohol in these cases is  $Pr.CH_2.CH_2.CH_2.OH$ .

*Formation*.—1. Through the acetate, from *n*-hexyl chloride which is formed, together with *sec*-hexyl chloride, by chlorinating hexane (Cahours a. Pelouze, C. R. 54, 1245; Schorlemmer, A. 161, 271).—2. By reducing the corresponding aldehyde with sodium-amalgam (Lieben a. Rossi, A. 133, 178; Lieben a. Janacek, A. 187, 126).

*Formyl derivative*  $C_6H_{13}OCHO$ . (146°). S.G.  $d_{20}^{20} = 0.8495$ . Smells like apples.

*Acetyl derivative*  $C_6H_{13}OAc$ . (170° i.V.). S.G.  $d_{20}^{20} = 0.889$  (F. a. Z.);  $d_{20}^{20} = 0.8902$ . C.E. (0°–10°).

·00100. S.V. 197·7 (Gartenmeister).

*Benzoyl derivative*  $C_6H_{13}OBz$ . (272°). S.G.  $d_{20}^{20} = 0.998$ . Oil, smelling like apples (Frentzel, B. 16, 745).

*Hexoyl derivative*  $C_6H_{13}O.CO.C_6H_{11}$ . (246°). S.G.  $d_{20}^{20} = 0.865$ .

*Ethyl ether*  $C_6H_{13}OEt$ . (134°–137°).

*Isohexyl alcohol*  $Pr.CH_2.CH_2.CH_2.OH$ . (150°). Formed by reducing the corresponding aldehyde with sodium-amalgam (Rossi, A. 133, 180).

Hexyl alcohol  $CH_3.CH_2.CH_2.CH_2.CH_2.OH$ . *β*-Ethyl-butyl alcohol. (154° cor.). S.G.  $d_{20}^{20} = 0.829$ .  $[\alpha]_D^{20} = 8.6^\circ$ . Obtained among the products of saponification of Roman oil of chamomile (Vay Komburgh, R. T. C. 5, 220). Gives on saponification a dextrorotatory hexoic acid and a hexyl hexoate (234°), S.G.  $d_{20}^{20} = 0.867$ ,  $[\alpha]_D = 12.86$  at 19°.

Hexyl alcohol  $CH_3.CH_2.CH_2.CH_2.CH_2.OH$ . *α*-Propyl-propyl alcohol. (147°). S.G.  $d_{20}^{20} = 0.8375$ . One of the products of the reduction of  $CH_3Et:CMc.CHO$ , and separated from the accompanying  $CH_3Et:CMc.CH_2OH$  by treatment with bromine and water, whereby the latter is changed to  $CH_3Et(OH).CMc(OH).CH_2OH$  (Lieben a. Zeisel, M. 4, 28). Optically inactive liquid. On oxidation with chromic acid mixture it yields  $CH_3Et.CHMe.CO_2H$  and methyl propyl ketone.

*Acetyl derivative*  $C_6H_{13}OAc$ . (162° cor.). S.G.  $d_{20}^{20} = 0.8717$ .

Hexyl alcohol  $Pr.CHMe.CH_2.OH$  (?). (153° i.V.). S.G.  $d_{20}^{20} = 0.830$ . Occurs as angelate and tiglate in Roman oil of chamomile (Kobig, A. 195, 102). Formed also from  $Pr.Pr$  by chlorination, &c. (Silva, B. 6, 147).

*Acetyl derivative*  $C_6H_{13}OAc$ . (155°–160°).

*Sec*-hexyl alcohol  $CH_3.CH_2.CH_2.CH_2.CHMe.OH$ . *Methyl-butyl-carbinol*. (β)-Hexyl alcohol. (187°) (E. a. W.); (141°) (S.). S.G.  $d_{20}^{20} = 0.833$ ;  $d_{20}^{20} = 0.821$ .

*Formation*.—1. By digesting (β)-hexyl iodide with water and  $Ag_2O$  (Wanklyn a. Erlennmeyer, C. J. 16, 221; Hecht, A. 165, 146), or with a large excess of boiling water (Niederist, A. 196, 351).—2. From the corresponding chloride which is formed together with *n*-hexyl chloride by chlorinating *n*-hexane (Schorlemmer, A. 161, 272).—3. From the mixture of chlorides obtained from *n*-hexane by conversion into hexylene and treatment with  $HCl$  (Morgan, A. 177, 307).—4. By converting (β)-hexyl iodide into hexylene, treating the product with  $H_2SO_4$  and distilling the resulting  $C_6H_{14}O.SO_3H$  with water (W. a. E.).—5. Formed also by treating hexylene from maninite with  $HOCl$  and reducing the product with iron filings and acetic acid (Domac, M. 2, 320; A. 213, 124).

*Properties*.—Thick liquid with pleasant odour, very unlike that of isomyl alcohol. Chromic acid mixture oxidises it to an aldehyde, and afterwards to butyric and acetic acids.

*Acetyl derivative*  $C_6H_{13}OAc$ . (156° cor.). S.G.  $d_{20}^{20} = 0.878$ .

*Ethyl ether*  $C_6H_{13}OEt$ . (188°). S.G.  $d_{20}^{20} = 0.776$ .

**Sec-hexyl alcohol**  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$ . *Methyl-sec-butyl-carbinol*. (184° E.V.). S.G.  $\frac{4}{25}$  .8307. Formed by reducing methyl sec-butyl ketone dissolved in wet ether by sodium. A pinacone  $\text{C}_{12}\text{H}_{22}\text{O}_2$  (249°) is also formed, and this, when warmed with dilute  $\text{H}_2\text{SO}_4$ , gives two pinacolines  $\text{C}_{12}\text{H}_{22}\text{O}$  (Wislicenus, A. 219, 319). Colourless oil.

**Sec-hexyl alcohol**  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{OH})\text{CH}_2\text{CH}_2\text{CH}_3$ . *Ethyl-propyl-carbinol*. (135° cor.). S.G.  $\frac{2}{20}$  .831;  $\frac{22}{20}$  .819. Formed by reducing ethyl propyl ketone by sodium-amalgam (Völker, B. 8, 1019; Oechsner de Coninck, Bl. [2] 23, 7; B. 9, 193). Gives on oxidation ethyl propyl ketone and propionic acid.

**Acetyl derivative**  $\text{C}_6\text{H}_{13}\text{OAc}$  (150°).  
**Hexyl alcohol**  $\text{C}_6\text{H}_{13}\text{O}$ . (138°). From dichloro-di-ethyl oxide  $\text{CH}_2\text{ClCH}_2\text{CHClOEt}$  by treatment with  $\text{ZnEt}_2$  and treatment of the resulting  $\text{CH}_3\text{EtCHEtOEt}$  with  $\text{HI}$ ,  $\text{KOAc}$ , and  $\text{KOH}$  successively (Lieben, A. 178, 22). Gives acetic and butyric acids on oxidation, and would therefore appear to be identical with methyl-butyl-carbinol.

**Ethyl ether**  $\text{C}_6\text{H}_{13}\text{OEt}$ . (131°). S.G.  $\frac{2}{20}$  .787;  $\frac{22}{20}$  .770.

**Sec-hexyl alcohol**  $(\text{CH}_3)_2\text{CCHMe.OH}$ .  
*Methyl-tert-butyl-carbinol*. [4°]. (120.5°). S.G.  $\frac{2}{20}$  .636. Formed by reducing the corresponding ketone (pinacol) with sodium-amalgam (Friedel a. Silva, C. R. 76, 226). Liquid smelling like camphor, solidifying in a freezing-mixture to a mass of long silky needles. Oxidised by chromic mixture to pinacol and tri-methyl-acetic acid.

**Acetyl derivative**  $\text{C}_6\text{H}_{13}\text{OAc}$ . (c. 142°).  
**Tert-hexyl alcohol**  $\text{CMeEt.OH}$ . *Methyl-di-ethyl-carbinol*. (123°). S.G.  $\frac{2}{20}$  .8237;  $\frac{25}{20}$  .8194;  $\frac{28}{20}$  .8104.

**Formation**.—1. By treating acetyl chloride with  $\text{ZnEt}_2$ , leaving the product for two days until it has become viscid; then heating to 100° and mixing with water (Butlerow, Bl. [2] 5, 17). 2. Together with hexylene, hexane, and other products by treating  $\text{CH}_3\text{CH}_2\text{CHMeEt}$  dissolved in alcohol with  $\text{WOAc}$  and zinc (Wislicenus, A. 219, 316).—3. From the corresponding iodide  $\text{CMeEt.I}$  and cold very dilute  $\text{KOH aq}$  (W.).—4. By acting on di-ethyl ketone (1 mol.) with  $\text{MeI}$  (3 mols.) and zinc, followed by water (Reformatsky, J. pr. [2] 36, 340). Colourless mobile liquid, smelling like tert-butyl alcohol. Chromic acid mixture oxidises it to acetic acid only.

**Acetyl derivative**  $\text{CMeEt.COAc}$ . (148° cor.). S.G.  $\frac{2}{20}$  .8824;  $\frac{25}{20}$  .8772;  $\frac{28}{20}$  .8679.

**Tert-hexyl alcohol**  $\text{CMe}_2\text{Pr.OH}$ . *Di-methyl-propyl-carbinol*. (115°) (B.); (123°) (J.). Formed by treating butyryl chloride with  $\text{ZnMe}_2$ , followed by water (Butlerow, Z. 1866, 617; Jawein, A. 195, 264). Rather viscid liquid, lighter than water, and somewhat soluble therein. Does not solidify at  $-38^\circ$ . Gives on oxidation acetic and propionic acids.

**Tert-hexyl alcohol**  $\text{CMe}_2\text{Pr.OH}$ . *Di-methyl-isopropyl-carbinol*. (113°) (P.); (117°) (Pavlov, A. 196, 123); (119°) (K.). S.G.  $\frac{2}{20}$  .836;  $\frac{12}{20}$  .823 (P.);  $\frac{2}{20}$  .837 (K.).  $\text{O.D.}$  (0°-50°) .00099.

**Formation**.—1. By treating isobutyryl chloride with  $\text{ZnMe}_2$ , followed by water (Pranischnikoff, Bl. [2] 16, 303).—2. From  $\alpha$ -bromo-pro-

pionyl bromide by successive treatment with  $\text{ZnMe}_2$  and water (Kaschirski, C. C. 1881, 278).—3. By acting on  $\text{ZnMe}_2$  (5 pts.) with chloral (2 pts.) (Rizza, Bl. [2] 38, 161).—4. From  $\text{ZnMe}_2$  and di-chloro-acetyl chloride, the yield being 6 p.c. (Bogomoletz, Bl. [2] 34, 330).

**Properties**.—Liquid, smelling of camphor, solidifying at  $-14^\circ$ . On oxidation with chromic acid mixture it gives acetone and acetic acid.

**References**.—Bromo- and Chloro-HEXYL-ALCOHOL.

(n)-HEXYLAMINE  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ . (129°). S.G.  $\frac{12}{20}$  .77. Occurs in cod-liver oil (Gautier a. Mourgues, C. R. 107, 254). Obtained from n-hexyl chloride (derived from n-hexane in petroleum) and  $\text{NH}_3$  (Pelouze a. Cahours, A. Ch. [4] 1, 5).

**Preparation**.—A mixture of equal mols. of the amide of hexoic acid and bromine is run into an excess of a 10 p.c. solution of  $\text{KOH}$  at 60°; the yield is 70 p.c. (Hofmann, B. 15, 771; Frenzel, B. 16, 744).— $\text{B.HCl}$ : laminae.— $\text{B}_2\text{H}_4\text{PtCl}_2$ : scales.

**Is-hexyl-amine**  $\text{Pr.CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ . From isohexyl iodide and alcoholic  $\text{NH}_3$  (Rossi, A. 133, 181).— $\text{B}_2\text{H}_4\text{PtCl}_2$ : scales.

(s)-Hexylamine  $\text{Pr.CH}_2\text{CHMe.CH}_2\text{NH}_2$ . (116° i.v.). S.G. .76. Formed, together with hexylene, by heating (s)-hexyl iodide with  $\text{NH}_3$  (Uppenkamp, B. 8, 56; Jahn, B. 15, 1292; M. 3, 170).— $\text{B}_2\text{H}_4\text{PtCl}_2$ : golden plates.

**Tert-hexylamine**  $\text{CMeEt.NH}_2$ . (109°). From the carbamine  $\text{CMeEt.NC}$  and  $\text{HCl aq}$  (Schdanoff, A. 185, 123).

**Di-n-hexyl-amine**  $(\text{C}_6\text{H}_{13})_2\text{NH}$ . (190°-195°). From alcoholic  $\text{NH}_3$  and n-hexyl chloride derived from n-hexane of petroleum (P. a. C.).

**Tri-n-hexyl-amine**  $(\text{C}_6\text{H}_{13})_3\text{N}$ . (260°). From n-hexyl chloride and alcoholic  $\text{NH}_3$  (P. a. C.). Formed also by distilling with lime the compound of Neptoe aldehyde (ananthol) with  $\text{NH}_3$  and  $\text{SO}_2$  (Petersen, A. 101, 310; 102, 312).— $\text{B.HCl}$ .— $\text{B}_2\text{H}_4\text{PtCl}_2$ : glittering laminae.

**Ethyl-iodide**  $(\text{C}_6\text{H}_{13})_2\text{NEtI}$ : liquid.

**HEXYL-BENZENE**  
 $\text{Ph.CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ . *Capryl-benzene*. (212°-213°) at 733 mm. S.G.  $\frac{19}{20}$  .857. From benzyl bromide, iso-amyl bromide, benzene, and sodium (Schramm, A. 218, 391; cf. Aronheim, A. 171, 223).

**Reaction**.—Bromine vapour at 150° forms  $\text{PhCHBr.CH}_2\text{CH}_2\text{CH}(\text{CH}_3)_2$ , which, on distillation, gives  $\text{HBr}$  and phenyl-hexylene, whose di-bromide  $\text{Ph.CHBr.CHBr.CH}_2\text{CH}_2\text{CHMe}_2$  forms needles or plates (79°-80°).

**Reference**.—Di-BROMO-HEXYL-BENZENE.

**n-HEXYL BROMIDE**  $\text{C}_6\text{H}_{13}\text{Br}$ . (156° cor.) S.G.  $\frac{2}{20}$  1.194;  $\frac{22}{20}$  1.173. From n-hexyl alcohol and  $\text{HBr}$  (Lieben a. Janacek, A. 187, 137).

**Hexyl bromide**  $\text{Pr.CHMe.CH}_2\text{Br}$ . (c. 144° cor.). From the corresponding alcohol and conc  $\text{HBr aq}$  at 130° (Lieben a. Zeisel, M. 4, 83). Converted by water (80 pts.) at 150° into hexylene.

**Sec-hexyl bromide**  $\text{Pr.CH}_2\text{CHMeBr}$ . [144° From boiling n-hexane and bromine (Scholemmer, A. 188, 260).

**HEXYL-CHLORAL** o. Tri-CHLORO-HEXO-ALDEHYDE.

**n-HEXYL CHLORIDE**  $C_6H_{13}Cl$  *i.s.*

$Pr.CH_2.CH_2.CH_2.Cl$ . *Chloro-hexane*. (133°) (Lieben a. Janacek, A. 187, 159; Frenzel, B. 16, 745). Formed, together with (8)-hexyl chloride, by chlorinating *n*-hexane (Cahours, C. R. 10, 1241).

**Sec-hexyl chloride**

$CH_3.CHCl.CH_2.CH_2.CH_2.$  (8)-*Hexylchloride*, (125°). From cold fuming  $HCl$  and hexylene; derived from *n*-hexane (got from mannite) by chlorination and subsequent treatment with alcoholic potash (C. Schorlemmer, Pr. 29, 365; T. 171, 452; Domac, M. 2, 313). Formed also, together with *n*-hexyl chloride, by chlorinating *n*-hexane (Schorlemmer, A. 161, 272), and by saturating (8)-hexyl alcohol with  $HCl$  and heating in a sealed tube at 100° (Erlenmeyer a. Wanklyn, C. J. 17, 190). With  $Pb(OAc)_2$  and glacial acetic acid at 125° it forms hexyl acetate  $C_6H_{13}OAc$ . If this is *ppd.* by water and saponified by strong potash an alcohol or mixture of alcohols (130°-140°) is got. This alcohol gives on oxidation acetic and butyric, but no propionic acid.

Hexyl chloride  $Pr.CHMe.CH_2.Cl$ . (124°). A product of the chlorination of *Pr.Pr* (Silva, Bl. [2] 6, 36; 7, 953).

Sec-hexyl chloride  $C_6H_{13}Cl$ . (117°). Formed by passing  $HCl$  through a mixture of conc.  $HClAq$  and the mixed hexylenes obtained by the action of alcoholic  $KOH$  upon the mixture of hexyl chlorides got by chlorinated *n*-hexane (Morgan, C. J. 28, 301). The same hexyl chloride is probably also got from the hexylene found among the products of the distillation of glycerin with  $NaOH$  (Fernbach, Bl. [2] 34, 146). The corresponding alcohol boils at 125°-129°, and gives on oxidation a ketone (c. 123°).

Sec-hexyl chloride  $C_6H_{13}Cl$ . (123°). Obtained by heating with  $HClAq$  for 10 hours at 135° the hexylene left uncombined in preparing the preceding hexyl chloride (M.). Probably identical with (8)-hexyl chloride. When heated with  $Pb(OAc)_2$  and  $HOAc$  at 120° it gives a hexyl acetate which, on saponification, yields a hexyl alcohol (132°-137°), which is oxidised by chromic acid mixture, even in the cold, to a ketone (125°).

Sec-hexyl chloride  $CMe_2.CHMe.Ch$ . (114°). S.G. 2.899; 25.875. From the corresponding alcohol and  $HCl$  (Friedel a. Silva, Bl. [2] 19, 289).

Tert-hexyl chloride  $CMe_2.Pr.Cl$ . (100°). From the alcohol and  $PCl_5$  (Butlerow, J. 1864, 497). Partially decomposed on distillation.

Tert-hexyl chloride  $CMe_2.Pr.Cl$ . [-2°]. (111°). S.G. 2.897; 25.878. From  $CMe_2.CMe_2$  and  $HCl$  (Pawloff, A. 196, 124; Kaschirski, C. C. 1881, 278). Also from *Pr.Pr* and  $Cl$  (Silva).

Tert-hexyl chloride  $CMe_2.Et.Cl$ . (110°). From the alcohol and  $PCl_5$  (Butlerow).

Hexyl chloride  $C_6H_{13}Cl$ . (122°). S.G. 14.8943. From di-isopropyl (hexane) *Pr.Pr* and chlorine (Schorlemmer, A. 144, 184). Silva (Bl. [2] 6, 36; 7, 953) obtained, however,  $CMe_2.Pr.Cl$ . (118°) and  $Pr.CHMe.CH_2.Cl$ . (124°).

**HEXYL-CYANIC ACID** *v.* **CYANIC ACID.****n-HEXYLENE**  $C_6H_{12}$  *i.e.*

$CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.$  *Butyl-ethylene*. (a)-*Hexylene*. Mol. w. 84. (69°). From *n*-hexyl

chloride and alcoholic  $KOH$  (Morgan, A. 177, 305; Schorlemmer, A. 190, 141). The same hexylene is perhaps formed by treating the di-hydro-di-iodide with sodium. It boils at 69°, and has S.G. 2.694 (Wurtz, A. Ch. [4] 3, 129). Greville Williams (T. 1847; A. 108, 384) found a hexylene boiling at 71° among the products of the distillation of Boghead coal. Thorpe and Young (A. 165, 8) obtained a hexylene boiling about 65° to 70° from strongly heated paraffin. *n*-Hexylene is among the products of the manufacture of oil gas (Armstrong, C. J. 49, 74).

**Properties.**—*n*-Hexylene does not combine with fuming  $HCl$  in the cold; but at 100° it forms hexyl chloride (123°). With bromide of nitrogen it forms a heavy oil (A. K. Miller, C. J. Proc. 3, 140).

(8)-Hexylene  $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.$  (69°) (W. a. B.); (67°) at 738 mm. (Hecht a. Strauss, A. 172, 62). S.G. 2.700. V.D. 2.92 (calc. 2.90). Obtained, apparently in the pure state, from the *n*-hexane derived from mannite by chlorinating and heating the resulting mixture of hexyl chlorides (121°-134°) with alcoholic  $KOH$  at 100° (Schorlemmer, Pr. 29, 368). Formed also by treating (8)-hexyl iodide with alcoholic  $KOH$  at 100° (Erlenmeyer a. Wanklyn, A. 135, 141; cf. Hecht, B. 11, 1050), and, together with the preceding, from the *n*-hexane of petroleum by chlorination, followed by treatment with alcoholic  $KOH$  (Morgan, A. 177, 305; C. J. 28, 301). Also from (8)-hexyl iodide and  $ZnMe_2$  at 125° (Purdie, C. J. 39, 465).

**Reactions.**—1. Combines with cold fuming  $HClAq$ ; the combination being complete in the course of a few weeks, the product being  $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.$  (125°) (Schorlemmer).—2.  $HI$  forms (8)-hexyl iodide (168°).—3. Chromic acid mixture oxidises it to *n*-butyric and acetic acids.—4.  $ClO_2$  gas (from  $KClO_3$  and  $H_2C_2O_4$ , 2 aq (1 pt.),  $H_2SO_4$  (1 pt.), and  $H_2O$  (2 pts.)) forms acetic and butyric acid, and a body that can be reduced by nascent hydrogen to secondary hexyl alcohol (Domac, A. 213, 124). 5.  $HClO$  gives  $C_6H_{13}Si(OH)$  (140°) (Domac, M. 2, 309).—6.  $H_2SO_4$  (3 pts.), diluted with water (1 pt.), dissolves (8)-hexylene, and on adding water (8)-hexyl alcohol is *ppd.*

Hexylene  $CMe_2.CMe_2$ . *Tetra-methyl-ethylene*. (73°). S.G. 2.712. Formed by the action of alcoholic  $KOH$  on  $CMe_2.Pr.I$  (Jawein, A. 195, 253; Pawloff, A. 196, 124; Rizza, J. R. 1892, 99; C. J. 42, 491). Formed also, together with a heptylene, by heating  $CMe_2.CHMe$  with  $PbO$  and  $Mel$  for eight hours at 225° (Eltekoft, J. R. 14, 380). Forms a dibromide  $C_6H_{12}Br_2$  (169°). A 10 p.c. solution of  $CrO_3$  completely oxidises tetra-methyl-ethylene to acetone. Butlerow (J. R. 11, 219) also obtained tri-methyl-acetic acid by oxidation.  $H_2SO_4$  (2 vols.), mixed with water (1 vol.), polymerises it to  $C_{12}H_{22}$  at 60°.

Hexylene  $CMe_2.CH_2.CH_2.$  (70°). From pinacol iodide by distillation with water (Friedel a. Silva, C. R. 76, 226). Forms a crystalline dibromide.

Hexylene  $CHMe.CMeEt$ . (70°). S.G. 7.12; 19.698. C.E. 00116. From  $CMeEt.I$  and alcoholic  $KOH$  (Tschaikowsky, J. 1872, 350) (Jawein, A. 195, 255). It is also a product of the action of zinc and glacial acetic acid, or  $CH_3.CH_2.CHMe.CHMeI$  (Wieland, A. 219

813). Combines with HI forming  $\text{CMeEt.I}$ . Chromic acid oxidises it with difficulty forming acetic acid and a small quantity of a ketone. By agitating the hexylene (1 vol.) with (2 vols. of) a mixture of  $\text{H}_2\text{SO}_4$  (2 pts.) and water (1 pt.) at  $0^\circ$  until it is dissolved, and subsequently exposing the solution to the air, there is formed an oily dodecylene  $\text{C}_{12}\text{H}_{24}$  (196°-199°); S.G. 2 809;  $\rho$  798. O.E. 00080.

Hexylene  $\text{CHEt.CMe}_2$ . (66°). S.G. 2 702;  $\rho$  687. C.E. 00117. From  $\text{CMe}_2\text{PrI}$  and alcoholic KOH (Jawein, A. 195, 255). Chromic acid oxidises it to acetic and propionic acids and acetone. Polymerised in the same manner as the preceding body, forming a, dodecylene  $\text{C}_{12}\text{H}_{24}$  (195°). S.G. 2 795;  $\rho$  786. C.E. 00065.

Hexylene  $\text{C}_6\text{H}_{12}$ . (60°-70°). Obtained by distilling fusel oil with  $\text{ZnCl}_2$  (Wurtz, A. 128, 228). Forms a dibromide  $\text{C}_6\text{H}_{10}\text{Br}_2$  (190°-200°).

Hexylene  $\text{C}_6\text{H}_{12}$ . (65°). S.G. 2 694. Obtained by distilling the lime-soap obtained from whale oil (Warren & Storer, Z. 1868, 228).

Hexylene  $\text{C}_6\text{H}_{12}$ . (67°-70°). In oil of resin (Renard, A. Ch. [6] 1, 227).

Hexylene  $\text{C}_6\text{H}_{12}$ . (70°-80°). *Dipranylene*. From propylene bromide, zinc, and  $\text{HOAc}$  (Frunier, C. R. 76, 98).

References.—Bromo- and Di-chloro-hexylene

$\text{O} \begin{smallmatrix} \text{CMe}_2 \\ \text{CMe}_2 \end{smallmatrix} \text{CMe}_2$ . (96°). Formed from  $\text{CMe}_2\text{CMe}_2$  by conversion into  $\text{CMe}_2\text{Cl.CMe}_2\text{OH}$  [55°] and treatment of this chloro-hexyl alcohol with KOH (Eltekoff, Bl. [2] 40, 23; J. R. 1882, 355). Combines with water with evolution of heat, the product being pinacone.

Hexylene oxide  $\text{C}_6\text{H}_{10}\text{O}$  i.e.

$\text{O} \begin{smallmatrix} \text{CHMe} \\ \text{CHPr} \end{smallmatrix} \text{CMe}_2$ . (110°). S.G. 2 8236. From ( $\beta$ )-hexylene  $\text{Pr.CH:CHMe}$ , by successive treatment with  $\text{ClOH}$  and conc.  $\text{KOH}$  (Eltekoff, Bl. [2] 40, 23; Henry, A. Ch. [5] 29, 553). Liquid. Does not combine with cold water, but at  $100^\circ$  it forms di-oxy-hexane  $\text{Pr.CH(OH).CH(OH)Me}$ . A mixture of  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  forms the nitrate  $\text{C}_6\text{H}_{11}(\text{NO}_3)_2$ .

Hexylene oxide  $\text{C}_6\text{H}_{10}\text{O}$  i.e.

$\text{O} \begin{smallmatrix} \text{CHMe.CH}_2 \\ \text{CHMe.CH}_2 \end{smallmatrix} \text{CMe}_2$ ? (93°). S.G. 2 837. S. 7 in the cold.

**Formation.**—1. Together with hexenyl alcohol, by the action of  $\text{Ag}_2\text{O}$  on the di-iodo-hydrate of diallyl (di-iodo-hexane) (Wurtz, A. Ch. [4] 3, 175).—2. By treating diallyl with  $\text{H}_2\text{SO}_4$  and distilling with water (Jekyll, Z. 1871, 36).

**Properties.**—Liquid, does not react with  $\text{NaHSO}_4$ , hydroxylamine, ammoniacal  $\text{AgNO}_3$ , cold  $\text{HCl}$ , or water at  $170^\circ$ . Does not ppt. a solution of  $\text{MgCl}_2$ . Sodium-amalgam does not reduce it.

**Reactions.**—1.  $\text{HCl}$  at  $150^\circ$  forms a chloro-hexyl alcohol ( $170^\circ$ - $180^\circ$ ) (Béhal, Bl. [2] 48, 43;

A. Ch. [6] 16, 200) and, finally, di-chloro-hexane. 2. Fuming  $\text{HIAg}$  at  $100^\circ$  forms *sec*-hexyl iodide. 3. *Chromic acid mixture* oxidises it to  $\text{CO}_2$  and acetic acid.—4. Excess of bromine forms di-bromo-hexane and an aldehyde.

Hexylene-3-oxide  $\text{O} \begin{smallmatrix} \text{CHMe.CH}_2 \\ \text{CH}_2 - \text{CH}_2 \end{smallmatrix} \text{CH}_2$ .

( $104^\circ$  at 720 mm.). S.G. 2 8739. Very mobile colourless liquid of strong ethereal smell. V. sol. alcohol and ether, sl. sol. water. Volatile with steam. Prepared by heating the glycol with 3 pts. of  $\text{H}_2\text{SO}_4$  (65 p.a.) at  $100^\circ$ . It is not affected by heating with water or with aqueous or alcoholic  $\text{NH}_3$ , even at  $200^\circ$ . By boiling with dilute  $\text{HCl}$  it is converted into the chlorhydrin (Lipp, B. 18, 3283).

Hexylene oxide  $\text{O} \begin{smallmatrix} \text{CH(CH}_2\text{Pr)} \\ \text{CH}_2 - \text{CH}_2 \end{smallmatrix} \text{CMe}_2$ ? (115°).

From  $\text{Pr.CH}_2\text{CH(OH).CMe}_2\text{CH(OH)}$  by conversion into the chlorhydrin (chloro-hexyl alcohol) and treatment of the latter with KOH (Wurtz, A. Ch. [4] 3, 184).

Hexylene oxide?  $\text{C}_6\text{H}_{10}\text{O}$ . (185°). From  $\text{PrPr}$  by conversion into  $\text{C}_6\text{H}_{11}\text{Br}$ , and treatment of this di-bromo-hexane with  $\text{AgOAc}$  and KOH successively (Silva, Bl. [2] 19, 147).

**HEXYLENIC ACID v. HEXENOIC ACID.**

**HEXYL-GLYCERIN v. TRI-OXY-HEXANE.**

**HEXYL-GLYCOL v. DI-OXY-HEXANE.**

**HEXYL-GLYOXALINE  $\text{C}_6\text{H}_{10}\text{N}_2$  i.e.**

$\text{C}_6\text{H}_4(\text{O}_2\text{C}_2\text{H}_5)_2$ . *Glyoxal- $\alpha$ -nanthylamine*. [84°] (Radziszewski, B. 16, 748); [51°] (Karcz, M. 8, 218). (295°). Prepared by the action of glyoxal on heptioic aldehyde-ammonia ( $\alpha$ -nanthol-ammonia) in alcoholic solution (R.), or by passing  $\text{NH}_3$  into a mixture of glyoxal and heptioic aldehyde (K.). Thin glistening needles; sol. alcohol, sl. sol. ether, insol. water. Karcz attributes the difference in the melting-point, as observed by himself and by Radziszewski, to the existence of two allotropic forms of the hexyl-glyoxaline.  $\text{MeI}$  gives  $\text{C}_6\text{H}_4\text{Me}(\text{C}_2\text{H}_5)_2\text{N}_2$  (262°);  $\text{EtI}$  and  $\text{PrI}$  act in like manner.

**Salts.**— $\text{B.HCl}$ : colourless deliquescent needles.— $\text{B}^+\text{HBr}$ .— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ . [121°].

**HEXYL HEPTADÉCYL KETONE  $\text{C}_{24}\text{H}_{48}\text{O}$  i.e.**  $\text{C}_6\text{H}_{11}\text{CO.C}_7\text{H}_{15}$ . (248°) at 10 mm. Formed by distilling barium stearate with barium heptate (Krafft, B. 15, 1713).

**HEXYL HYDRIDE v. HEXANE.**

**n-HEXYL IODIDE  $\text{C}_6\text{H}_{13}\text{I}$  i.e.**

$\text{Pr.CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$  (177°) (Dobriner, A. 248, 27); (179°) (Franchimont, A. Zincke, A. 163, 196); (182° cor.) (Lieben & Janacek, A. 187, 189). S.G.  $\frac{3}{4}$  14661 (D.);  $\frac{1}{2}$  1412 (F. & Z.);  $\frac{1}{4}$  1461 (L. & J.). C.E. (0°-10°) 00095 (E.). S.V. 173-8. Prepared from *n*-hexyl alcohol and HI.

Hexyl iodide  $\text{C}_6\text{H}_{13}\text{I}$ . (172°-175°). S.G. 2 143. Obtained from petroleum hexane *vis* hexyl alcohol (Pelouze & Cahours, C. R. 54, 1241).

*Sec*-hexyl iodide  $\text{C}_6\text{H}_{13}\text{I}$  i.e.  $\text{Pr.CH}_2\text{CH(OH).CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$ . (168° i.v.). S.G. 2 145;  $\frac{1}{2}$  14269;  $\frac{3}{4}$  14168 (Perkin, C. J. 45, 463). C.E. (0°-50°) 00092. M.M. 14429 at 23-9°.

**Formation.**—1. By boiling mannite or dulcitate with a great excess of conc.  $\text{HIAg}$  (Wanklyn & Erlennmeyer, Z. 1861, 606; 1862, 641).—2. By the action of HI on ( $\beta$ )-hexylene obtained by treating the di hydro-di-iodide of diallyl with

sodium (Wurtz, A. 132, 306).—3. From hexylene oxide (93°) and HI (Jekyll, C. N. 22, 221).

**Preparation.**—1. Mannite (24 g.) is distilled with aqueous HI (300 c.c. boiling at 126°) and clear phosphorus in a current of CO<sub>2</sub>. The yield is nearly the theoretical (E. a. W.).—2. Iodine (75 g.) and water (130 g.) are treated, in an atmosphere of CO<sub>2</sub>, with clear phosphorus until colourless; mannite (25 g.) is then added, and the mixture distilled in a current of CO<sub>2</sub> (Domac, M. 2, 310; cf. Hecht, A. 165, 148).—3. A mixture of mannite (200 g.) and red phosphorus (100 g.) is added slowly to HIAq (500 g. of 57 p.c.), and the mixture distilled in a current of CO<sub>2</sub> (Hecht, A. 209, 311).—4. A good yield is obtained by distilling mannite with fuming HIAq and a little amorphous phosphorus (Schorlemmer, T. 171, 452).

**Properties.**—Liquid, smells like isoamyl iodide.

**Reactions.**—1. *Alcoholic potash* gives (β)-hexylene.—2. By heating with water at 190° it gives hexylene. By boiling for a long time with a large excess of water (45 pts.) *sec*-hexyl alcohol is the chief product, hexylene being also formed (Mederist, A. 196, 351).—3. With moist Ag<sub>2</sub>O, with zinc and water, with zinc and alcohol, with silver oxalate, with sodium, with mercury, and with ZnMe<sub>2</sub>, it yields hexylene.—4. When (β)-hexyl iodide (100 g.) is heated with iodine (25 g.) for 5 hours to 256° it yields hexane, HI, a little MeI, and a combustible gas (Rayman a. Preis, A. 223, 322).—5. *Chloride of iodine* at 240° gives hexa-chloro-benzene, CCl<sub>6</sub>, C<sub>2</sub>Cl<sub>4</sub>, and C<sub>3</sub>Cl<sub>8</sub> (Krafft, B. 9, 1085).—6. *Chromic acid* mixture oxidises it to acetic and butyric acids (Hecht, B. 11, 1421).

*Sec*-hexyl iodide C<sub>6</sub>H<sub>13</sub>I i.e. Pr.CHEtI (?) *Di-ethylated ethyl iodide*. (100°) at 70 mm. From di-chloro-di-ethyl oxide CH<sub>3</sub>Cl.CHCl.OEt via CH<sub>3</sub>Et.CHEt.OEt (Lieben, A. 178, 18). Probably identical with the following.

*Sec*-hexyl iodide Pr.CHEtI. (165°). From the alcohols and HI (Oechsner de Coninck, Bl. [2] 25, 9).

*Sec*-hexyl iodide CHMeEt.CHMeI. From the corresponding hexyl alcohol and HI (Wislicenus, A. 219, 310). Liquid; decomposed on distillation. Zinc and acetic acid reduce it to CHMeEt.CHMe, a hexylene, and a dodecylene, some methyl-di-ethyl-carbinol being also formed.

*Sec*-hexyl iodide (CH<sub>3</sub>)<sub>2</sub>C.CHMeI. (142°). S.G. d 1.474; n<sub>D</sub> 1.442. From the corresponding alcohol and PI (Friedel a. Silva, C. R. 76, 226). Partially split up on distillation with water into HI and a hexylene (70°).

Hexyl iodide C<sub>6</sub>H<sub>13</sub>I. (c. 150°). Formed by combination of HI with the hexylene derived from fusel oil (Wurtz, A. 128, 229).

*Tert*-hexyl iodide CMeEt<sub>2</sub>I. (142°). Formed by leaving equal volumes of methyl-di-ethyl-carbinol and fuming HIAq to stand in the cold. Formed also from CH<sub>3</sub>.CH.CMeEt and HI (Wislicenus, A. 219, 318; Tschalkowsky, J. 1872, 850; Reformatsky, J. pr. [2] 86, 340). Liquid; partially decomposed on distillation.

*Tert*-hexyl iodide CMe<sub>2</sub>PrI. (142°). Formed by the action of HI on di-methyl-propyl-carbinol or on CMe<sub>2</sub>.CHET (Jawein, A. 195, 254).

*Tert*-hexyl iodide CMe<sub>2</sub>PrI. (142°). S.G. d 1.394; n<sub>D</sub> 1.373. From CMe<sub>2</sub>.CMe<sub>2</sub> and HI

(Pawloff, A. 196, 125). Solidifies at 0° (Kaschirski, C. C. 1881, 278). Slightly decomposed by distillation.

*DI-HEXYL KETONE* C<sub>12</sub>H<sub>26</sub>O i.e. (C<sub>6</sub>H<sub>13</sub>)<sub>2</sub>CO. [30°].  $\gamma$ 264° cor.). S.G.  $\gamma$ 825. Formed by the dry distillation of calcium heptate (enan-thoate) (Uslar a. Seekamp, A. 108, 179). Large colourless laminae (from alcohol).

*Sec-HEXYL-MALONIC ACID* C<sub>8</sub>H<sub>16</sub>.CH(CO<sub>2</sub>H)<sub>2</sub>. [c. 86°]. From the ether by saponification. Nodules, v. sol. water, alcohol, and ether.

*Ethyl ether Et<sub>2</sub>A''*. (251°). From sodium malonic ether and (β)-hexyl iodide (Lundahl, B. 16, 789).

*n*-(?)-HEXYL MERCAPTAN C<sub>6</sub>H<sub>13</sub>.SH. (145°–148°). From petroleum hexane by conversion into hexyl chloride followed by treatment with KSH (Pelouze a. Cahours, A. 124, 291).

*Sec*-hexyl mercaptan Pr.CH<sub>2</sub>.CHMe.SH. (142°). S.G. d 886. From (β)-hexyl iodide and conc. alcoholic KSH (Wanklyn a. Erlenmeyer, A. 135, 150). Colourless oil, with unpleasant smell.—Hg(SC<sub>6</sub>H<sub>13</sub>)<sub>2</sub>. Liquid. S.G. d 1.650.

HEXYL-NITROUS ACID so-called.

C<sub>6</sub>H<sub>13</sub>.N<sub>2</sub>O<sub>4</sub>. (212°). S.G.  $\gamma$  1.1381. Formed by the action of HNO<sub>3</sub> on methyl-hexyl ketone (Chancel, C. R. 94, 399; 100, 601). Oil, slightly decomposed by distillation. May be reduced to *n*-hexoic acid.—C<sub>6</sub>H<sub>13</sub>.KN<sub>2</sub>O<sub>4</sub>: slender yellow plates (from water); sl. sol. water. Decomposes without detonation when heated. The silver salt is a similar body.

*DI-sec-HEXYL OXIDE* (C<sub>6</sub>H<sub>13</sub>)<sub>2</sub>O. (204°–209°). Formed, together with a hexylene and hexyl alcohol, by the action of moist Ag<sub>2</sub>O on (β)-hexyl iodide (Erlenmeyer a. Wanklyn, Z. 1863, 274). Thick yellowish oil.

HEXYL-PARACONIC ACID v. OXY-HEPTYL-SUCCINIC ACID.

HEXYL PENTADECYL KETONE C<sub>21</sub>H<sub>42</sub>O i.e. C<sub>6</sub>H<sub>13</sub>.CO.C<sub>15</sub>H<sub>31</sub>. (231°) at 10 mm. Formed by distilling a mixture of barium palmitate and barium heptate (Krafft, B. 15, 1718).

HEXYL SULPHIDE (C<sub>6</sub>H<sub>13</sub>)<sub>2</sub>S. (230°). From petroleum hexane via hexyl chlorides (Pelouze a. Cahours, A. 124, 291). Oil.

HEXYL SULPHOCYANIDE C<sub>6</sub>H<sub>13</sub>.SCy (215°–220°). S.G. d 922. Formed by heating potassium sulphocyanide at 100° with an alcoholic solution of hexyl chloride derived from petroleum (Pelouze a. Cahours, A. Ch. [4] 1, 5). Fetid liquid.

*Sec*-hexyl sulphocyanide Pr.CH<sub>2</sub>.CHMe.SCy (207°). Prepared by boiling equal parts of (β)-hexyl iodide with potassium sulphocyanide dissolved in alcohol (Uppenkamp, B. 8, 55). Oil with alliaceous odour.

*n*-HEXYL THIOCARBIMIDE C<sub>6</sub>H<sub>13</sub>.NCS (212°). Formed by distilling cupric *n*-hexyl-di-thio-carbamate with steam (Frentzel, B. 16, 746). Pungent oil.

*Sec*-hexyl thiocarbimide Pr.CH<sub>2</sub>.CHMe.NCS (198°). S.G.  $\gamma$  92. From (β)-hexylamine by boiling with CS<sub>2</sub> and alcohol, evaporating, and heating the residue with a solution of mercuric chloride (Uppenkamp, B. 8, 56). Oil. Converts by hot conc. H<sub>2</sub>SO<sub>4</sub> into (β)-hexylamine.

*n*-HEXYL THIO-UREA C<sub>6</sub>H<sub>13</sub>.N<sub>2</sub>S i.e. CS(NH<sub>2</sub>)(NH.C<sub>6</sub>H<sub>13</sub>). [83°]. From *n*-hex-

thiocarbimide and alcoholic  $\text{NH}_3$  (Frentzel, B. 1, 746). White plates (from alcohol).

**Di-*n*-hexyl thio-urea**  $\text{CS}(\text{NH}_2\text{C}_6\text{H}_{13})_2$  [40%]. Obtained by heating *n*-hexylammonium *n*-hexylthio-carbamate (F.). White plates (from alcohol).

**HEXYL-TRIDECYL-KETONE**  $\text{C}_{25}\text{H}_{50}\text{O}$  i.e.  $\text{C}_6\text{H}_{13}\text{COOC}_9\text{H}_{19}$ . (210° at 11 mm.). Formed by distilling a mixture of barium heptoste and barium myristate (Krafft, B. 15, 1717).

**HEXYL-UREA. Heptyl derivative**  $\text{C}_6\text{H}_{13}\text{NH.CO.NH.CO.C}_7\text{H}_{15}$  [97%]. Formed by the action of KOH on a mixture of the amide of heptioic (senanthioic) acid and bromine (Hofmann, B. 15, 769). Pearly plates; insol. water.

**Sec-hexyl-urea**  $\text{NH}_2\text{CO.NH.OHMe.C}_6\text{H}_{13}\text{Pr}$  [127%]. (c. 220°). From (*β*)-hexyl iodide and silver cyanate, the resulting thiocarbimide being decomposed by shaking with aqueous ammonia (Chydenius, Bl. [2] 7, 481). Slender needles (from water); v. sol. water, alcohol, and ether. Not decomposed by conc. KOHq below 200°.

**HIPPARRAFIN** v. *Dibenzoyl derivative of METHYLENE-DIAMINE*.

**HIPPURIC ACID**  $\text{C}_9\text{H}_7\text{NO}$ , i.e.  $\text{NEBz.CH}_2\text{CO}_2\text{H}$ . *Benzoyl-glycocol.* *Benzoyl-amido-acetic acid.* *Benzamido-acetic acid.* Mol. w. 179. [187%]. S.G. 1.308 (Schabus, Sitz. W. 1850, 211). S. 17 at 0°. S. (isoamyl alcohol) 2 at 9°; 33 on boiling (Campani, B. 11, 1247).

**Occurrence.**—1. In the urine of herbivorous animals and in small quantity (c. 1 g. daily) in that of man (Liesbig, A. 12, 20; Henneberg, Stohmann a. Rautenberg, A. 124, 181; Bence Jones, C. J. 15, 81; Thudichum, C. J. 17, 55; Weismann, J. pr. 74, 106; Wreden, J. pr. 77, 446; Hofmeister, L. V. 14, 458; Wildt, B. 6, 1410; Kraut, C. C. 1858, 881; Loew, J. pr. [2] 19, 809; Stadelmann, J. 1879, 982; Schwarz, A. 54, 32; Weiske, Wildt a. Pfeiffer, B. 6, 1410; Hallwachs, A. 106, 164; E. Salkowski, B. 11, 500; Weyl a. Aurep, B. 13, 1092; Garrod, Pr. 35, 63; 37, 148; Minkowski, J. 1883, 1440).—2. In the blood of oxen (Verdeil p. Dollfus, A. 74, 214).—3. In the human epidermis in ichthyosis (Schlossberger, A. 93, 347).

**Formation.**—Y. Excreted by the animal organism after introduction of benzoic acid (Bouis a. Ure, B. 5, 22, 567; Ure, J. Ph. 27, 646; Keller, A. 43, 108; Garrod, P. M. [3] 20, 501). Quinic acid (Lautemann, A. 125, 9), cinnamic acid (Erdmann a. Marchand, B. J. 23, 646) toluene (Naunyn c. Schultzen, Z. 1868, 29), and phenyl-propionic acid also yield hippuric acid when passed through the animal organism. Since phenyl-propionic acid is produced by the pancreatic fermentation of proteids, hippuric acid is, at any rate in part, due to the decomposition of proteids (E. a. H. Salkowski, B. 12, 654; Baumann, H. 10, 131).—2. From benzoyl chloride and zinc glycocol or from glycocol and benzoic acid at 100° (Dessaignes, C. R. 37, 251). The yield is very bad.—3. From chloroacetic acid and benzamide (Jazukowitch, Bl. [2] 8, 861). The yield is bad.—4. By heating glycocol with benzoic anhydride (Curtius, Z. 17, 1662).—4. From silver glycocol and BzCl (Curtius, J. pr. [2] 26, 170).—5. By adding benzoyl chloride to an aqueous solution of glycocol and making alkaline with NaOH (Baum, B. 19, 502).

**Preparation.**—1. The urine of horses or cows is boiled with addition of some milk of lime, filtered, neutralised by HCl, evaporated, acidified by HCl and allowed to stand. Hippuric acid is then deposited as a yellowish-brown pp (Gregory, A. 63, 126; cf. Riley, C. J. 5, 97). When horses' urine is quickly evaporated the hippuric acid is partly converted into benzoic acid. Crude hippuric acid, obtained as above is then mixed with rather less water than will dissolve it at 100°. The liquid is then heated to 100° and chlorine passed in until the unpleasant odour of the crude product has disappeared. The liquid is filtered hot, and the acid that separates on cooling is subjected a second time to the same treatment, chlorine being passed in this time until the liquid is bright yellow. The yield is 65 p.c. of the crude acid (T. Curtius, J. pr. [2] 26, 149; cf. Daube, A. 74, 202; Conrad, J. pr. [2] 15, 242; Gössmar, A. 99, 374; Schwarz, A. 54, 29; Hansen, J. 7, 1881, 117).—2. Silver glycocol is suspended in a mixture of benzene (1 vol.) and ether (2 vols.) and benzoyl chloride is added. On warming AgCl is formed together with several acids. The liquid is evaporated and benzoic acid removed by solution in ether. Three nitrogenous acids remain. They are dissolved in NaOH, reprecipitated by HCl, dried and extracted thoroughly with chloroform. This dissolves the hippuric acid, which is present in greatest quantity. One of the remaining acids is hippuryl-glycocol (q. v.) (Curtius, J. pr. [2] 26, 168). The other has the formula  $\text{C}_{10}\text{H}_7\text{N}_3\text{O}_6$ . Both these acids split up with formation of hippuric acid when they are heated with dilute HCl.

**Properties.**—Crystallises from water in very large trimetric prisms;  $a:b:c = 974:1161:1$ . Has a slightly bitter taste, and strongly reddens litmus. Sl. sol. cold, v. sol. boiling water. V. sol. hot alcohol, v. sl. sol. ether. Less soluble in water containing HCl, and hence is ppd. on adding a considerable excess of HCl to cow's urine. Dissolves readily in water containing sodium phosphate, the solution becoming acid; in this respect it resembles uric acid. Insol. benzene,  $\text{CS}_2$ , and cold chloroform. Sol. EtOAc. FeCl<sub>3</sub> forms, in a dilute solution of an alkaline hippurate, a cream-coloured pp. of basic ferric hippurate  $\text{Fe}_2\text{A}_2\text{Fe}_2\text{O}_4 \cdot 1\frac{1}{2}\text{aq}$ , which is moderately soluble in excess of ferric chloride (E. Salkowski, Z. [2] 4, 813).

**Estimation in urine.**—1. Recently calcined MgO is added to 1 litre of urine, the liquid is concentrated, acidified with HCl and extracted with ether (A. W. Blyth, Pr. 37, 50).—2. 250 c.c. of urine are evaporated to 80 c.c., 4 g. of sodium phosphate are added, and the evaporation continued to syrupy consistence. Plaster of Paris is then added till the mass can be powdered, after which it is extracted first with light petroleum and then with ether. The ethereal extract is evaporated, and the hippuric acid decolourised with charcoal, crystallised from water, and weighed (Voelker, Fr. 26, 402).

**Reactions.**—1. On heating to 240° hippuric acid begins to boil, giving off benzoic acid and benzonitrile (Gössmann, A. 100, 69; Limpriohrt a. von Usler, A. 88, 188).—2. Boiling aqueous hydrochloric acid splits it up into benzoic acid and glycocol. Dilute  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , and oxalic acid

behave in like manner.—8. By boiling for half an hour with aqueous *caustic potash* it is resolved into glycoooll and potassium benzoate. Boiling milk of lime does not effect its hydrolysis.—4. Some ferments hydrolyse hippuric acid (Buchner, *A.* 78, 283).—5. *Nitrous acid* converts it into the benzoyl derivative of glycollic acid, with evolution of nitrogen.—6. When boiled with NaOBr and an excess of alkali for a long time, a bright-red powder is deposited on cooling (Denigès, *C. R.* 107, 662).—7. HCl and KClO<sub>4</sub> form chloro- and di-chloro-hippuric acids (Otto, *A.* 122, 129).—8. A cold mixture of H<sub>2</sub>SO<sub>4</sub> and HNO<sub>3</sub> forms nitro-hippuric acid.—9. SO<sub>3</sub> gives sulpho-hippuric acid.—10. *Chlorine* passed into a solution of hippuric acid in dilute KOH forms benzoyl-glycollic acid, nitrogen being evolved (Gössmann).—11. The prolonged action of PCl<sub>5</sub> forms C<sub>6</sub>H<sub>5</sub>·NCl<sub>2</sub>, probably hexa-chloro-isquinoline tetrahydride C<sub>6</sub>H<sub>4</sub>· $\begin{smallmatrix} \text{CCL}_2\text{CHCl} \\ \text{CCL}_2\text{NCl} \end{smallmatrix}$  [134°] (Rügheimer, *B.* 19, 1169). This body crystallises in plates. By distilling hippuric acid (1 mol.) with PCl<sub>5</sub> (2 mols.) Schwanert (*A.* 112, 59) obtained C<sub>6</sub>H<sub>4</sub>ClNO [50°] (220°) and C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>NO.—12. Boiling with MnO<sub>2</sub> and very dilute H<sub>2</sub>SO<sub>4</sub> forms benzoic acid, NH<sub>3</sub>, and CO<sub>2</sub>.—13. When heated with PbO<sub>2</sub> and excess of HNO<sub>3</sub> or H<sub>2</sub>SO<sub>4</sub> the product is the di-benzoyl derivative of methylene-diamine (hipparaffin).—14. Boiling with water and PbO<sub>2</sub>, with addition of only enough H<sub>2</sub>SO<sub>4</sub> to combine with the lead, produces benzamide (Fehling, *A.* 28, 48; Schwagz, *A.* 75, 190).—15. *Ozone* oxidises it to benzoic and acetic acids (Gorup-Besanez, *A.* 125, 217).—16. By boiling with KMnO<sub>4</sub> and KOH all the nitrogen is expelled as NH<sub>3</sub> (Wanklyn a. Chapman, *C. J.* 21, 161).—17. A concentrated aqueous solution of ZnCl<sub>2</sub> at 120° forms benzoic acid and glycoooll. Distillation with dry ZnCl<sub>2</sub> gives benzonitrile (Gössmann, *A.* 100, 69).—18. *Sodium amalgam* added to an alkaline solution of hippuric acid forms 'hydrobenzuria acid' C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>3</sub> and 'hydrobenzyluric acid' C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>4</sub>; the latter dissolves in ether, the former does not (Otto, *A.* 134, 303). Both acids give glycoooll when boiled with alkalis; the latter forms also benzyl alcohol and hydrobenzoic acid.—When hydrobenzyluric acid is heated with alkalis and at the same time exposed to the air, there is formed 'hydroxybenzyluric acid' C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>4</sub> (60°–70°), which when left in a desiccator over H<sub>2</sub>SO<sub>4</sub> changes to an acid C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>4</sub>.—19. *Pyruvic acid* (6 g.) digested with sodium hippurate (11 g.) and Ac<sub>2</sub>O (25 g.) at 100° forms a compound C<sub>12</sub>H<sub>9</sub>N<sub>2</sub>O<sub>4</sub> which crystallises from petroleum in flat needles [157°], v. sol. alcohol, ether, and HOAc, insol. water. It seems to be an anhydride, for baryta forms the salt C<sub>12</sub>H<sub>7</sub>BaNO<sub>4</sub> 2aq (A. Hoffmann, *B.* 19, 2554).—20. By mixing hippuric acid with salicylic aldehyde and excess of Ac<sub>2</sub>O and allowing the mixture to stand for some weeks there is formed a compound C<sub>22</sub>H<sub>15</sub>N<sub>2</sub>O<sub>4</sub> [160°] (Plöchl a. Wolfram, *B.* 18, 1184). Rebuffat (*G.* 15, 527) by boiling sodium hippurate (62 g.) with salicylic aldehyde (40 g.) and Ac<sub>2</sub>O (20 g.) obtained a compound C<sub>18</sub>H<sub>11</sub>N<sub>2</sub>O<sub>4</sub> which crystallised from alcohol in canary-yellow prisms [136°], and is converted by hot aqueous (10 p.c.) KOH into benzoyl-imido-coumarin C<sub>11</sub>H<sub>7</sub>N<sub>2</sub>O<sub>4</sub> [171°] and an

acid C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>4</sub> [185°].—21. *Phthalic anhydride* yields a compound C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>4</sub> (E. Erlenmeyer, *jun.*, *B.* 22, 792).

**Salts.**—NH<sub>4</sub>HA' aq: formed even in presence of excess of NH<sub>3</sub>. Square-based prisms with four-sided summits, v. sol. water and alcohol, sl. sol. ether. Gyrates when thrown on the surface of water.—KA' aq: prisms, sol. water and alcohol.—KA'HA' aq.—NaA' ½ aq: v. sol. hot water and alcohol, sl. sol. ether.—BaA' ½ aq: prisms, sol. water; forms with barium benzoate the double salt BaA'·Ba(OBz)<sub>2</sub> 5aq.—CaA' ½ aq: trimetric prisms. S. 5·6 in the cold; 17 at 100°. S.G. 1·32.—SrA' ½ aq: sl. sol. cold water and alcohol.—MgA' ½ aq: white nodules, sol. water.—ZnA' ½ aq: laminae. S. (of ZnA') 1·8 at 17·5°; 25 at 100°.—CuA' ½ aq: azure prisms, sl. sol. cold water.—PbA' ½ aq: silky needles, deposited on diluting a boiling solution.—PbA' ½ aq: broad laminae.—CoA' ½ aq: rose-coloured needles.—NiA' ½ aq: sl. sol. cold, m. sol. boiling water and boiling alcohol, insol. ether.—CeA' ½ aq (Czudnovitch, *J. pr.* 82, 277).—LaA' ½ aq (Czudnovitch, *J. pr.* 80, 31).—FeA' (Wreden, *C. C.* 1859, 552).—Fe(OH)A' (Salkowski, *J. pr.* 102, 327; c.f. Putz, *J.* 1877, 795).—AgA' ½ aq: may be crystallised from water.

*Methyl ether* MeA'. [80·5°]. S. 85 in the cold; 1·3 at 30°. Formed by passing HCl into a solution of hippuric acid in methyl alcohol at 60° (Jacquemin a. Schlagdenhauffen, *C. R.* 45, 1011; Conrad, *J. pr.* [2] 15, 247; Campani a. Bizzari, *G.* 10, 260). White needles. Decomposed at 250°, giving off NH<sub>3</sub> and benzonitrile.

*Ethyl ether* EtA'. [60°]. S.G. 82 1·043. Formed by passing HCl into a boiling alcoholic solution of hippuric acid (Stenhouse, *A.* 31, 148), or by heating amido-acetic ether with benzoic anhydride (Curtius, *B.* 17, 1662). White needles, sl. sol. hot water, v. sol. ether. When hippuric ether (5 pts.) is heated with dry NaOEt (1 pt.) to 160°, alcohol distils over, and there is left a mixture of two sodium salts, which may be separated by water. The less soluble salt, when decomposed by HCl, yields the di-benzoyl-derivative of di-oxy-di-amido-tetramethylene:

[153·5°–159·5°] (Rügheimer, *B.* 21, 3325). When hippuric ether is heated with PCl<sub>5</sub> for eight hours at 160°, and the product poured into alcohol, 'hippurroflavin' separates. It crystallises from hot HOAc in small yellow crystals, and partially decomposes, without melting, at 300°. Hippurroflavin is v. sl. sol. glacial HOAc, and almost insol. water, alcohol, and ether. It

has perhaps the constitution  $\begin{smallmatrix} \text{NHBz.C.CO} \\ \text{CO.C.NHBz} \end{smallmatrix}$

(Rügheimer, *B.* 21, 3321).

• *n-Butyl ether* PrCH<sub>2</sub>A'. [41°]. From silver hippurate and *n*-butyl iodide (C. a. B.). Iridescent prisms, insol. water, sol. alcohol, ether, and chloroform.

*Isobutyl ether* PrCH<sub>2</sub>A'. [46°]. From AgA' and isobutyl iodide in presence of isobutyl

alcohol (C. a. B.). Iridescent prisms. Decomposed by damp air.

*Isocamyl ether*  $C_6H_5A'$ . [28°].

*Benzyl ether*  $PhCH_2A'$ . [86°]. From  $AgA'$  and benzyl bromide (Del Zanna a. Guareschi, *Atti Real. Istit. Veneto* [5] 6). Silky needles. Converted by  $HNO_3$  into benzoic aldehyde.

*Amide*  $C_6H_5NO.NH_2$ . [188°]. S. 1 in the cold. Formed by the prolonged action of aqueous ammonia on methyl hippurate (Jacquemin a. Schlagdenhauffen, *C. R.* 45, 1011). Formed also by heating hippuric acid in a current of  $NH_3$  at 160° (Conrad, *J. pr.* [2] 15, 248). Small thick crystals, v. sl. sol. cold water, alcohol, and ether. Forms an unstable compound with  $HCl$ .

*Uride*  $NH_2Bz.CH_2.CO.NH.CO.NH_2$ . [216°]. Formed, together with another compound [189°], by heating ethyl hippurate with urea at 150° (Curtius, *B.* 16, 757); and by heating hippuric acid with alcoholic  $NH_3$  at 220° (Pellizzari, *C. C.* 1888, 1350). Silvery plates; decomposed by boiling dilute acids into hippuric acid and urea. Split up by alcoholic  $NH_3$  at 260°, giving benzamide and  $EtOBz$ .

*References*.—AMIDO-, BROMO-, CHLORO-, IODO-, NITRO-, OXY-, and SULPHO-HIPURIC ACID.

**HIPPURYL-GLYCOCOLL**  $C_{11}H_{17}N_2O_4$ , i.e.  $Bz.NH.CH_2.CO.NH.CH_2.CO_2H$ . [207°].

*Preparation*.—Silver glycooll (40 g.), benzoyl chloride (15.5 g.), and benzene (200 c.c.) are heated together until  $HCl$  begins to come off. The product is evaporated, extracted with ether, then with  $NaOH$ . The mixed acids are ppd. by  $HCl$ , dried and exhausted with alcohol. The alcoholic extract leaves on evaporation a mixture of hippuric acid and hippuryl glycooll. The greater part of the former may be removed by chloroform, and the hippuryl glycooll is then purified by recrystallising 20 or 30 times from 30 p.c. alcohol (Curtius, *J. pr.* [2] 26, 170). In this reaction benzoyl chloride acting on silver glycooll forms silver chloride and hippuric acid. This hippuric acid acts upon benzoyl chloride forming benzoic acid and hippuryl chloride, which then attacks silver glycooll, forming silver chloride and hippuryl-glycooll.

*Properties*.—Satiny trimetric plates (from water). The crystals are small, and feel fatty. Insol. ether,  $CHCl_3$ , benzene, and  $CS_2$  in the cold, but sl. sol. these solvents when boiling. Readily sol. boiling dilute (30 p.c.) alcohol.

*Reactions*.—1. Boiled with  $HCl$  or  $KOH$  it gives glycooll (2 equivalents) and benzoic acid (1 equivalent).—2. At 150° in a sealed tube with an aqueous solution containing the calculated quantity of  $HCl$  it splits up into glycooll and hippuric acid.

*Salts*.— $AgA'$ : white crystalline pp., sol. hot water without reduction.— $TiA'$ : six-sided tablets.— $BaA'$ , 5aq (?) Little plates.— $CaA'$ , 3½aq: trimetric prisms.— $ZnA'$ , 1½aq.

*Ethyl ether EtA'*. [117°]. Large needles (from water).

*Amide*  $BzNH.CH_2.CO.NH.CH_2.CO.NH_2$ . [202°]. Forms an unstable compound with  $HCl$  which is at once resolved by water into its constituents.

**HISTO-HEMATINS** v. MUSCLE.

**HOFMANN'S VIOLET** v. PENTA-METHYL-TRIAMIDO-DI-PHENYL-TOLYL-CARBINOL.

**HOMO-ANISIC ACID** v. *Methyl derivative of OXYTOLIC ACID*.

**HOMO-BENZ-AMIDOXIM** v. TOLU-AMIDOXIM.

**HOMO-CINCHONIDINE** v. CINCHONA BASES.

**HOMO-FERULIC ACID** v. *m-Methyl derivative of (4:3:1)-Di-OXY-PHENYL-CROTONIC ACID*.

**HOMOLOGOUS SERIES**. A series of closely related compounds of which the molecules differ from one another by  $CH_2$  or a multiple thereof. Homology is usually the result either (a) of the introduction of one or more methyl radicles in place of the equivalent quantity of hydrogen, or (b) of the insertion of a methylene group between two contiguous carbon atoms; thus benzoic acid  $C_6H_5.CO_2H$  is homologous with toluic acid  $C_6H_4(CH_3).CO_2H$  in the first way, and with phenyl-acetic acid  $C_6H_5.CH_2.CO_2H$  in the second way. In each homologous series there is a nearly constant difference in the properties of any two successive members of the series; this rule, however, does not apply to the difference between the first and second members, particularly where the first member does not contain  $CH_2$ . Although the alkyl derivatives of hydroxylic compounds differ from these compounds by a multiple of  $CH_2$ , and might therefore be considered homologous with the parent substance, yet as they belong to the group of ethers while their parents are acids or alcohols, this cannot be considered a case of true homology.

**HOMO-NICOTINIC ACID** v. METHYL-PYRIDINE CARBOXYLIC ACID.

**HOMO-OXY-BENZOIC ACID** v. OXY-TOLUIC ACID.

**HOMO-PHENACYL-ANILIDE** v. *ω*-PHENYL-AMIDO-PHENYL-ETHYL KETONE.

**HOMO-PHTHALIC ACID** v. CARBOXY-PHENYL-ACETIC ACID.

**HOMO-PROTocatechuic ACID** v. Di-OXY-PHENYL-ACETIC ACID.

**HOMOPYROCATECHIN**, *Methyl ether of, v. CREOSOL*.

**HOMO-PYRROLE** v. METHYL-PYRROLE.

**HOMOQUININE** v. CINCHONA BASES.

**HOMOSALICYLIC ACID** v. OXY-TOLUIC ACID.

**HOMO-VERATRIC ACID** v. *Di-methyl derivative of Di-OXY-PHENYL-ACETIC ACID*.

**HOPEINE**  $C_{15}H_{25}NO$ , aq. S. 125 at 15°. An alkaloid said to occur to the extent of .15 p.c. in American wild hops, and of .05 p.c. in English hops (Williamson, *J. Ph.* [5] 12, 460; *Chem. Zeit.* 10, 491). Brilliant white needles (from dilute alcohol). Narcotic. Sublimes partially below 160°. Slightly levorotatory. Its dilute solutions are ppd. by alkalis,  $PtCl_3$ ,  $AuCl_3$ ,  $HgCl_2$ , picric acid, and tannin. According to Ladenburg (*B.* 13, 788), hopeine is identical with morphine, or is a mixture of morphine with an alkaloid that gives no colour with  $FeCl_3$  or with  $H_2SO_4$  and molybdic acid, and is insol.  $NaOH$  aq. v. sol. wet ether.

*Lupuline*. According to Griessmayer (*D. P. J.* 212, 67), when the aqueous extract of hops is distilled with lime or magnesia the distillate contains  $NH_3$ , trimethylamine, and an alkaloid lupuline. If the bases be converted into hydrochlorides, and these be treated with alcohol,  $NH_3$  is left undissolved, while  $NMe_3.HCl$  crystallises from the evaporated alcoholic solution, and the mother liquor contains lupuline

hydrochloride. The base may be obtained by decomposing its hydrochloride with KOH and haking with ether. It smells like coniine, has a cooling, but not bitter, taste, and gives the usual reactions of alkaloids. Conc.  $\text{H}_2\text{SO}_4$  and potassium chromate give a violet colour.  $\text{HNO}_3$  gives a yellow solution, becoming green or blue at its edges, and afterwards colourless.

**HOP OIL.** At the base of the membranous cones of the hop there is a bitter yellow powder called lupulin. This powder contains resin, wax, a tannin, and a bitter principle also called LUPULIN (*q.v.*). When distilled with steam it yields hop oil, which consists of a terpene  $\text{C}_{10}\text{H}_{16}$  (175°), and various compounds containing oxygen (Wagner, *D. P. J.* 128, 217; Personne, *J. Ph.* [3] 26, 241, 329; 27, 22; Kuhnemann, *C. C.* 1875, 573). One of the oxygenated constituents of oil of hops is converted into valeric acid by oxidation.

**HUMIC ACID.** The brown or black substance, or mixture of substances, produced by the decay of vegetable matter. The decomposition is promoted by heat, air, moisture, and by the presence of putrefying nitrogenous matter. Humic acid may be extracted from peaty soil by aqueous  $\text{Na}_2\text{CO}_3$  and ppd. by  $\text{HCl}$  (Mulder, *A.* 36, 243; Detmer, *L. V.* 14, 248). Detmer assigned the formula  $\text{C}_{20}\text{H}_{16}\text{O}_{10}$  to humic acid, and described it as amorphous, beginning to decompose at 145°, and requiring 8,333 parts of water at 6°, or 625 at 100°, to dissolve it. After drying it required 13,784 parts of boiling water for solution. It reddened litmus, expelled  $\text{CO}_2$  from its salts, and formed the following amorphous salts:— $(\text{NH}_4)_2\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . *S.* 45. —  $\text{Ca}_2(\text{NH}_4)_2\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . —  $\text{Fe}_2(\text{NH}_4)_2\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . —  $\text{Ag}_2\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . P. Thénard (*C. R.* 83, 375) described humic acid as  $\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . 'Ulmic' acid prepared from brown peat is identical with humic acid. Crenic and apocrenic acids (*q.v.*) are, perhaps, products of oxidation of humic acid. Thénard obtained it by dissolving crude humic acid in potash ppg. with a slight excess of  $\text{HCl}$ , washing the pp. well, and keeping the spongy mass at  $-14^\circ$  for 24 hours. As the mass thaws the humic acid separates as a dense pp. Humic acid is not capable of converting atmospheric nitrogen into  $\text{NH}_3$  (Prevost, *C. J.* 39, 370; cf. Simon, *Instit.* 1875, 133; Déhérain, *C. R.* 73, 1352). Lettenmayer (*B.* 7, 408) observed that a piece of rotten beech-wood which had fallen into a cleft of the tree protected from the rain, was covered with a brittle black layer readily soluble in cold water, and was composed of the  $\text{K}$ ,  $\text{Na}$ , and  $\text{NH}_4$  salts of an acid (? humic) containing 53.6 p.c.  $\text{O}$  and 4.9 p.c.  $\text{H}$ . When cane sugar is boiled for a long time with dilute  $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ , there is produced a substance greatly resembling humic acid, called SACCHARIC ACID (*q.v.*). A brown substance is formed by heating cellulose with water in a platinum tube at 200°; and brown substances are formed by the action of alkalis on glucose, cane-sugar, and many other substances. If all these brown bodies are included in the term humous substances, they may be subdivided into three groups: (a) those insol. alcohol and alkalis; (b) those insol. alcohol but sol. alkalis; (c) those soluble both in alcohol and alkalis (Hoppe-Seyler, *H.* 18, 66).

**HYENIC ACID**  $\text{C}_{23}\text{H}_{40}\text{O}_2$ . Mol. w. 382. [78°]. The glyceride of this acid is said to occur together with palmitin and olein in the anal glandular pouches of the striped hyena (Carius, *A.* 129, 168). According to Schulze a. Ulrich (*B.* 7, 570), it also occurs in the product of the saponification of the grease of sheep's wool. Granules composed of minute curved needles (from alcohol); resembles cerotic acid; sl. sol. cold alcohol, v. sl. sol. ether. Ppd. by alcoholic lead acetate sooner than palmitic acid. —  $\text{CaA}'_2$ : [90°]; white crystalline powder. —  $\text{PbA}'_2$ : white pp.

**HYALINS** v. PROTEIDS, Appendix C.

**HYALOGENS** v. PROTEIDS, Appendix C.

**HYDANTOIN**  $\text{C}_4\text{H}_4\text{N}_2\text{O}_2$  i.e.

$\text{CO} \begin{smallmatrix} \text{NH} \cdot \text{CH}_2 \\ \text{NH} \cdot \text{CO} \end{smallmatrix}$ , Glycollityl-urea. Di-oxy-methyl-pyrazole. Mol. w. 100. [215°].

**Formation.**—1. Together with urea, by the action of conc.  $\text{HIAq}$  at 100° on allantoin (Baeyer, *A.* 117, 179; 130, 158).—2. Together with a small quantity of allanturic acid, by the action of  $\text{HI}$  on alloxanic acid (*B.*).—3. By the action of an excess of alcoholic  $\text{NH}_3$  on bromo-acetyl bromide (Baeyer, *B.* 8, 612).

**Properties.**—Colourless needles, m. sol. cold, v. sol. hot, water. Neutral to litmus. Has a somewhat sweet taste. Not attacked by boiling dilute acids, but converted by boiling baryta-water into hydanitic acid. May be oxidised to allanturic acid. Ammoniacal  $\text{AgNO}_3$  gives a pp. of  $\text{AgC}_4\text{H}_4\text{N}_2\text{O}_2$  aq.

Hydanitic acid  $\text{C}_4\text{H}_4\text{N}_2\text{O}_2$  i.e.

$\text{NH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{H}$ . Uridido-acetic acid. Glycolluric acid.

**Formation.**—1. By boiling hydanitic acid with baryta-water or potash (Baeyer, *A.* 130, 160).—2. Together with urea, by boiling glycolluric  $\text{C}_4\text{H}_4\text{N}_2\text{O}_2$  with baryta-water (Rheinck, *A.* 134, 222).—3. By heating glycolluric acid with a slight excess of urea at 120° (Heintz, *A.* 133, 70; Griess, *B.* 2, 106).—4. By the action of cyanic acid on glycolluric acid; i.e. by heating glycolluric sulphate with potassium cyanate, ppg. potassium sulphate by alcohol, and allowing the liquid to evaporate spontaneously (Wislicenus, *A.* 165, 103).—5. By heating glycolluric acid with urea, or, better, by boiling these substances with baryta-water (Baumann a. Hoppe-Seyler, *B.* 7, 34).

**Properties.**—Monoclinic prisms;  $\alpha:b:c = .662:1: .535$ ;  $\beta = 81^\circ$ . M. sol. cold water and alcohol, v. sol. hot water and alcohol, nearly insol. ether.

**Reactions.**—1. Decomposed by heating with conc.  $\text{HIAq}$  at 165° to  $\text{CO}_2$ ,  $\text{NH}_3$ , and glycolluric (Menschutkin, *A.* 153, 105).—2. Pure  $\text{HNO}_3$  forms a nitro-derivative, no gas being evolved (Franchimont, *R. T. C.* 6, 217).

**Salts.**—These are all, except the  $\text{Ag}$  salt, v. sol. water.— $\text{KA}'$ : minute, six-sided tables and rhombohedra.— $\text{NaA}'$  aq: extremely soluble silky needles.— $\text{NH}_4\text{A}'$  aq: large crystals, becoming opaque from loss of  $\text{NH}_3$ .— $\text{BaA}'_2$  2aq (at 100°): amorphous, insol. alcohol.— $\text{PbA}'_2$  3aq: nodules.— $\text{AgA}'$ : pearly scales.

**References.**—ETHYL-, METHYL-, PHENYL-, PHENYL-METHYL-, STYRYL-, NITRO- and THIO-HYDANTOIN and HYDANTOIN ACID.

**HYDRACIDS.** As explained in the article ACIDS (vol. i. p. 47) those compounds of hydrogen which, in presence of water, react with metallic

oxides, hydroxides, and carbonates, and exchange the whole of their hydrogen, or a portion of it, for metal, are called *acids*. The element common to all acids is hydrogen; but it is only when hydrogen is intimately associated in a compound with one or more strongly negative elements that the compound has the properties of an acid. The greater number of acids contain oxygen, but the presence of this element is not necessarily accompanied by acidic function, nor is its absence proof that we have to deal with a non-acidic compound. Solutions of the following compounds contain acids: HF, HCl, HBr, HI, HCN, HSCN, HSeCN,  $\text{H}_2\text{Fe}(\text{CN})_6$ ,  $\text{H}_2\text{Fe}(\text{CN})_5$ ,  $\text{H}_2\text{Co}(\text{CN})_6$ ,  $\text{H}_2\text{Co}(\text{CN})_5$ ,  $\text{H}_2\text{Au}(\text{CN})_4$ ,  $\text{H}_2\text{Ir}(\text{CN})_6$ ,  $\text{H}_2\text{Mn}(\text{CN})_6$ ,  $\text{H}_2\text{Os}(\text{CN})_6$ ,  $\text{H}_2\text{Pt}(\text{CN})_6$ ,  $\text{H}_2\text{Ru}(\text{CN})_6$ ,  $\text{H}_2\text{Pt}(\text{SCN})_6$ ,  $\text{H}_2\text{Pt}(\text{SCN})_5$ ,  $\text{H}_2\text{AuCl}_4$ ,  $\text{H}_2\text{HgI}_4$ ,  $\text{HBF}_4$ ,  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{SnS}_4$ ,  $\text{H}_2\text{OS}_2$ . These acids, and a few more, do not contain oxygen. Acids which are not compounds of oxygen are sometimes classed together as *hydracids*. The name is more particularly applied when it is desired to distinguish between two classes of compounds of the same elements, or group of elements, both of which classes are acids, but only one class is formed of oxygen compounds; thus we speak of the oxyacids and the hydracids of the halogen elements. The terms hydracid is then only a convenient word when we wish to emphasise the fact that an acid under consideration is not an oxygen compound. All acids are hydracids, as all are compounds of hydrogen. M. M. P. M.

#### HYDRACRYLIC ACID $\text{C}_3\text{H}_3\text{O}_3$ , i.e.

$\text{CH}_2(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ .  $\beta$ -Oxy-propionic acid. Ethylene-lactic acid. (g). Lactic acid.

**Formation.**—1. By digesting  $\beta$ -iodo-propionic acid with excess of moist  $\text{Ag}_2\text{O}$ , decomposing the resulting silver salt by  $\text{H}_2\text{S}$ , filtering, neutralising with  $\text{Na}_2\text{CO}_3$ , and evaporating (Beilstein, A. 122, 366; Sokoloff, A. 150, 167). Acrylic, dihydracrylic  $\text{C}_4\text{H}_5\text{O}_3$ , and the isomeric para-adipo-malic acids (v. vol. i. p. 63) are formed, but are left undissolved when sodium hydracrylate is dissolved in 95 p.c. alcohol (Wislicenus, B. 4, 522; A. 166, 6).—2. Together with acrylic acid by boiling  $\beta$ -iodo-propionic acid with milk of lime. The impure acid may be converted into the zinc-calcium salt, which can be purified by recrystallisation, and then decomposed by  $\text{H}_2\text{S}$  and the calculated quantity of oxalic acid (Heintz, A. 157, 291).—3. By boiling  $\beta$ -iodo-propionic acid with a large excess (25 pts.) of water (Thomson, A. 200, 81).—4. By boiling sodium acrylate with aqueous  $\text{NaOH}$  (Linneemann, B. 8, 1095; Erlenmeyer, A. 191, 281).—5. From glycol chlorhydrin and KCN, followed by saponification of the product (Wislicenus, A. 123, 4; Erlenmeyer, A. 191, 268).—6. From ethylene oxide and HCN and saponification of product (Erlenmeyer, A. 191, 269).

**Properties.**—Strongly acid syrup, resolved by heat into water and acrylic acid. Unlike lactic acid it does not yield iodoform when heated with iodine and potash (Lieben's reaction).

**Reactions.**—1. Boiling with  $\text{H}_2\text{SO}_4$  (1 pt.) diluted with water (1 pt.) converts it into water and acrylic acid.—2. Chromic acid oxidises it to  $\text{CO}_2$  and oxalic acid. Nitric acid acts in like manner.—3.  $\text{Ag}_2\text{O}$  oxidises it to oxalic and glycollic acids.—4. Potash-fusion gives formic and acetic acids.—5. HI gives  $\beta$ -iodo-propionic acid.

**Salts.**— $\text{NaA}'$ : [148°]; flat deliquescent prisms, sl. sol. boiling alcohol. At 250° it gives acrylic and para-adipo-malic acids (Wislicenus, A. 174, 286).— $\text{CaA}'_2$ : [140°–146°]; prisms, very easily soluble in cold water, insol. alcohol. Forms with calcium acrylate a compound  $\text{Ca}(\text{C}_3\text{H}_3\text{O}_3)(\text{C}_3\text{H}_3\text{O}_2)$  aq.— $\text{ZnA}'_2$ : [60°]; triclinic crystals.  $\text{Q}$ . 112 at 16.5° (Wislicenus).— $\text{CaZnA}'_2$ : crystalline pp. formed on mixing the concentrated solutions of the zinc and calcium salts. S. 9 at 15°. Scarcely more soluble in hot than in cold water. Insol. boiling alcohol and ether.— $\text{AgA}'$ : delicate prisms and needles, v. sol. cold water, insol. alcohol.

**Nitrile**  $\text{CH}_2(\text{OH})\text{CH}_2\text{CN}$ . Glycol cyanhydrin. (221°) at 724 mm. S.G.  $\rho$  1.059. S. (ether) 2.3 at 15°. From ethylene oxide and dry HCN at 55° (Erlenmeyer, A. 191, 273). In liquid, miscible with alcohol and water.

#### Dihydracrylic acid $\text{C}_4\text{H}_5\text{O}_3$ , i.e.

$\text{O}(\text{CH}_2\text{CH}_2\text{CO}_2\text{H})_2$ . One of the products obtained by boiling  $\beta$ -iodo-propionic acid with  $\text{Ag}_2\text{O}$  and water (Wislicenus, A. 166, 39).— $\text{NaA}'$ : silky crystalline mass; insol. 95 p.c. alcohol, sol. hot 90 p.c. alcohol. Converted by HI into  $\beta$ -iodopropionic acid. Its aqueous solution gives with lead nitrate a flocculent pp., sol. excess.

**HYDRAMIDES.** Compounds of the form  $\text{N}_2\text{H}_4$ , obtained by the action of ammonia on certain aldehydes, chiefly aromatic, e.g. furfuraldehyde and benzoic aldehyde. They are crystalline solids, insol. water, sol. alcohol. They are not volatile, and are decomposed by acids into  $\text{NH}_3$  and the parent aldehyde.

**HYDRASTINE**  $\text{C}_{10}\text{H}_{15}\text{NO}_3$ . [132°] (F. A. W.).  $[\alpha]_D = -67.8^\circ$  (2.5 g. dissolved in 100 c.c. chloroform);  $+127^\circ$  in  $\text{HClAq}$ . An alkaloid discovered by Perrins (Ph. [2] 3, 546) in the root of *Hydrastis canadensis*, or Golden Seal, in which it exists to the amount of 1½ p.c., together with berberine, and possibly a third alkaloid, canadine (Van der Espt, Ph. [3] 3, 604; Hale, Ph. [3] 4, 105; Burt, Ph. [3] 6, 467; Lloyd, Ph. [3] 10, 125; Freund a. Will, B. 19, 2797; 20, 88, 2400; Schmidt a. Wilhelm, Ar. Ph. [3] 26, 329; Eijkman, R. T. C. 5, 290; Power, Ph. [3] 15, 297; 16, 1092; Lyons, Ph. [3] 16, 880; Mahla, Ann. S. [2] 36, 57). Occurs also in *Stylophorum diphyllum* (Eijkman).

Hydrastine is best obtained by extracting the root of *Hydrastis* with ether, and recrystallising the extract from alcohol (F. A. W.). Trimetric crystals,  $a:b:c = 846:1:376$ . Almost insol. water, al. sol. cold alcohol, v. sol. boiling alcohol and chloroform. It has a bitter taste, producing a feeling of numbness in the mouth. It does not appear to be poisonous.

**Reactions.**—1. Boiling dilute nitric acid forms opianic acid and hydrastinine.  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  give the same products.—2.  $\text{KMnO}_4$  in presence of  $\text{KCl}$ , also forms opianic acid.—3.  $\text{KMnO}_4$  in alkaline solution forms hemipic acid and pyridine carboxylic (nicotinic) acid.— $\text{B}'\text{HCl}$ — $\text{B}'\text{H}_2\text{PtCl}_6$ — $\text{B}'(\text{HAcCl})_6$ — $\text{B}'\text{H}_2\text{SO}_4$ —Picrate.  $\text{B}'\text{O}_2\text{H}_2(\text{NO}_2)_2\text{OH}$  aq.: yellow needles (from alcohol).

**Methylo-iodide**  $\text{B}'\text{MeI}$ . [208°]. Needles (from water or alcohol). With moist  $\text{Ag}_2\text{O}$  it gives crystals [237°].

**Ethylo-iodide**  $\text{B}'\text{EtI}$ . [206°] (S. A. W.); [124°] (Eijkman); [183°] (Power). Gives rise to

(B'EtCl), PtCl, [207°]. B'EtClAuCl, [c. 110°], and B'EtOH, which may be crystallised from hot water.

**Hydrastinine**  $C_{11}H_7NO$ , aq or  $C_{11}H_7NO$ , i.e.  $CHO.C_6H_4.OH.CH_2.NHMe$  (?) (W. Roser, A. 249, 156). [117°]. Obtained, together with opianic acid, when hydrastine is treated with oxidising agents (F. a. W.). White needles (from ligroin), v. e. sol. alcohol and ether, m. sol. hot water. Crystallises from all solvents with aq. Somewhat decomposed when recrystallised from benzene or EtOAc. Its aqueous solution is strongly alkaline and intensely bitter. Ppd. from its solution in acids by KOH but not by  $NH_3$  or  $Na_2CO_3$ . Reduced by Zn and HCl to hydrastinine dihydride. Boiling aqueous KOH forms hydrastinine dihydride and oxyhydrastinine. MeI forms a volatile base and an indifferent oil which yields an oxim [129°].

**Salts.**—B'HCl: [c. 223°]; needles, v. sol. alcohol and water. Its aqueous solution shows a feeble fluorescence, and is optically inactive. —B'H<sub>2</sub>SO<sub>4</sub>: sol. alcohol. —B'H<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>: slender golden needles, sol. water. Decomposes at 175°. —B'H<sub>2</sub>PtCl<sub>6</sub>.

**Methyl-iodide** B'MeI: slender yellow needles, sol. water and alcohol.

**Oxim**  $C_{11}H_7NO.CH:NOH$ . [140°]. Formed by boiling the base (1 g.) with hydroxylamine hydrochloride ( $\frac{1}{2}$  g.) and alcohol (20 c.c.) for a few minutes, and then adding  $NH_4$ Aq (Freund, B. 22, 457). Needles (from alcohol). —B'H<sub>2</sub>PtCl<sub>6</sub>: crystalline pp.

**Hydrastic acid**  $C_6H_5NO_3$ . [232°]. Formed by boiling hydrastine with dilute  $HNO_3$  until KOH no longer ppts. the product. Crystalline, sol. alcohol and water. Resembles apophyllin acid.—AgA': needles.

**Hydro-hydrastinine**  $C_{11}H_7NO_2$ , i.e.

$C_6H_5O < \begin{smallmatrix} CH_2.NMe \\ CH_2.CH_2 \end{smallmatrix} > (?)$  (Roser). [66°]. Formed by reducing hydrastine with zinc and HCl. White crystals, v. e. sol. alcohol, ether, benzene, and  $CS_2$ . Re-oxidised by chromic acid mixture to hydrastine.

**Salts.**—B'HCl: [274°]; crystals, sl. sol. water. —B'H<sub>2</sub>PtCl<sub>6</sub>: [216°]; yellow scales. —B'4HBr: [272°]; tufts of small white needles sl. sol. water. —B'HI: [232°]. —B'H<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>: red scales; explodes at 150°.

**Ethyl-iodide** B'EtI: [207°]; needles.

**Oxy-hydrastinine**  $C_{11}H_7NO$ , i.e.

$C_6H_5O < \begin{smallmatrix} CO.NMe \\ CH_2.CH_2 \end{smallmatrix} > (?)$  (Roser). [98°]. (above 350°). Formed, together with the preceding, by the action of aqueous KOH upon hydrastinine. Prepared by rubbing up hydrastinine with water and potash-ley, shaking, and adding a cold, saturated solution of  $KMnO_4$ , till decolourisation proceeds slowly; then filtering, extracting the residue with ether, neutralising, and evaporating the filtrate (Mörrin Freund, B. 22, 457). Needles, v. e. sol. alcohol, chloroform, and benzene. Feeble base. By dissolving in dilute  $HNO_3$ , it is converted into a crystalline nitro-derivative  $C_{11}H_7(NO_2)NO$ , [271°], insol.  $HCl$ , ammonia, or  $Na_2CO_3$  Aq, sol. warm  $NaOHAq$ . —B'HCl: [138°]; crystalline. Decomposed by water and by alcohol. —B'H<sub>2</sub>PtCl<sub>6</sub>: [160°]; yellow needles. —B'H<sub>2</sub>AuCl<sub>4</sub>: [100°]; reddish-brown mass.

**Dibromo-hydrastinine**  $C_{11}H_7Br_2NO$ , [c. 280°]. Formed by exposing a solution of the hydrobromide of hydro-hydrastinine to bromine vapour (Freund). Broad white needles (from hot water). In solutions of its salts  $NH_3$ , caustic soda, and  $Na_2CO_3$ , give a pp. which crystallises from alcohol in slender thread-like needles [125°].

• **Di-iodo-hydrastinine hydriodide** (so-called)  $C_{11}H_7I_2NO.HI$ . [184°]. A substance formed by boiling hydrastinine for some minutes with fuming  $HI$ Aq (Freund). Crystallises from alcohol in splendid brown needles.

**Constitution.**—Narcotine  $C_{18}H_{21}(OMe)_2NO$ , is perhaps methoxy-hydrastine, hydrastine being  $C_{11}H_7(OMe)_2NO$ . Hydrastinine would then contain no methoxyl, while cotarnine would be methoxyl-hydrastinine (Schmidt a. Wilhelm, *Ar. Ph.* [3] 26, 329).

**HYDRATES.** Compounds of water with other compounds or with elements. If Cl is passed into ice-cold water a yellowish white solid is produced, which when dried between paper at 0° forms a white mass of crystals having the composition  $Cl.5H_2O$ ; heated to 35° in a closed tube the crystals separate into Cl and water, and on cooling to 15° the compound  $Cl.5H_2O$  is again produced. The compound  $Cl.5H_2O$  is a hydrate of Cl, i.e. it is a compound of Cl with water. When BaO is brought into contact with water combination occurs, and  $BaO.H_2O$  is produced; this compound is not changed by the action of heat alone. It is customary to call  $BaO.H_2O$  an hydroxide, and to regard it as a compound of Ba, O, and H, rather than a compound of BaO with  $H_2O$ . If water is added to CaO (an oxide very similar to BaO), combination occurs, and  $CaO.H_2O$  is produced; at a full red heat this compound is resolved into its constituents, CaO and  $H_2O$ . The compound formed by the union of CaO and  $H_2O$  is sometimes called a hydrate, and its formula is written  $CaO.H_2O$ ; but by some chemists it is called an hydroxide, and the formula assigned to it is  $CaO.H_2$  or  $Ca(OH)_2$ . Compounds formed by the union of molecules of  $H_2O$  with other molecules or atoms, without a rearrangement of the atoms of the group  $H_2O$ , are called hydrates; compounds formed by a reaction of molecules of  $H_2O$  with other molecules or atoms, such that the group  $H_2O$  is separated into its constituent atoms, which are rearranged in the new molecule, are called hydroxides. But it is often impossible to tell whether a given compound is an hydrate or an hydroxide. The definition given above is a theoretical definition; we have no certain means of telling to which class a specified substance belongs. Another way of stating the theoretical difference between hydrates and hydroxides is to say that hydrates contain water as such, and that hydroxides contain the elements of water. Another form of words sometimes used is to speak of *water of hydration*, or *water of crystallisation*, and to contrast this with *water of constitution*. Cane sugar, for instance, has the composition  $C_{12}H_{22}O_{11}$ . Did we know nothing about cane sugar except its composition we might write the formula  $C_{12}H_{22}O_{11}$  as  $C_{12}H_{11}H_2O$ ; but the properties of cane sugar make it evident that it is not a compound of carbon with water, but a compound of C, H, and O, in which the H and O are in the

same ratio as in  $H_2O$ . We may say of cane sugar that it is an hydroxide, or that it contains the elements of water, or that it contains water of constitution. Copper sulphate,  $CuSO_4$ , combines with water to form blue crystals  $CuSO_4 \cdot 5H_2O$ ; when these crystals are heated to  $220^\circ$  or so, the water is all removed, and white  $CuSO_4$  remains; these changes—hydration and dehydration—may be repeated indefinitely. We may say then that the blue crystals of copper sulphate contain water of crystallisation.

The term hydroxide is sometimes used in a narrower sense than explained above; by some chemists it is applied only to compounds whose reactions are best explained by supposing them to contain the group or radicle  $OH$ .<sup>2</sup>

The problem suggested by the terms hydrate and hydroxide is not one merely of nomenclature; it is a typical problem of chemistry. The two terms attempt to summarise certain conceptions regarding connexions between the properties and the composition of certain compounds. Here, as in other chemical problems, we must study composition and properties, and we must beware of divorcing the one study from the other.

When Zn reacts with dilute  $H_2SO_4$  to form  $ZnSO_4$ , we know that the  $ZnSO_4$  must contain the zinc as such; yet the properties of the Zn are modified by its combination with the radicle  $SO_4$ . The  $ZnSO_4$  produced is a substance by itself; it has its own properties very different from those of any of its constituents. In a sense it is hardly accurate to say that zinc sulphate contains zinc; zinc sulphate is a new thing in which the properties of Zn, S, and O are merged. Zinc sulphate is as distinctly a definite homogeneous kind of matter as any of the elements which combine to form it. From it we can obtain Zn, S, and O; none of these three kinds of matter have we yet been able to separate into unlike parts. But when water combines with other substances, we are dealing with a body which we are able to separate into unlike parts; and, therefore, we may suppose either that the water combines as a whole with the other substance, or that a rearrangement of the atoms of the reacting bodies occurs, and that in the new compound the relation of the O and H atoms are different from those which hold good in the molecule  $H_2O$ .

The problem is similar to that presented by questions about the presence of this or that radicle, or group of atoms, in the molecules of carbon compounds; it also presents analogies with questions regarding molecular and atomic compounds. We cannot, as a rule, isolate the radicles which, we suppose, form groups of closely related atoms in the molecules of carbon compounds; we can, however, isolate the radicles which form groups of closely related atoms in the molecules, or at least in the chemically reacting weights, of double salts (v. DOUBLESALTS, p. 414). We can isolate the radicle, or group of atoms,  $H_2O$ ; the molecule, or the chemically reacting weight, of a hydrate is supposed to be so constituted that one of its radicles is the group  $H_2O$ ; whereas this group is supposed to be absent from the molecule of an hydroxide. If a compound is a hydrate we should expect it to reveal its constitution by its

properties and reactions: the radicle  $H_2O$  will carry with it certain characteristic properties different from those which belong to the radicle  $OH$ .

The methods by which attempts are made to differentiate hydrates from hydroxides consist partly in studying the chemical reactions of the compounds, and partly in determining their physical properties and comparing these with those of well-defined compounds belonging some to one class and some to the other.

Compounds formed by the reactions of water with other compounds or elements, and which are separated by heat into water and the other constituent from which they have been produced, are usually, but not in every instance, classed as hydrates. Some compounds are decomposed by heat with production of water and another substance, but are not produced by the direct union of water with the other substance; some of these compounds are classed as hydrates, some are not. Thus the compound  $CuO \cdot H_2O$ , which is decomposed by heat to  $CuO$  and  $H_2O$ , is generally regarded as hydrated copper oxide,  $CuO \cdot H_2O$ ; it is obtained by ppg. a solution of a Cu salt by an alkali, but it is not formed by the direct union of  $CuO$  and  $H_2O$ . But the compound  $AsO_3H_2$  is not called a hydrate, although it is resolved by heat into  $As_2O_3$  and  $H_2O$  ( $2H_2AsO_3 = As_2O_3 + 3H_2O$ ).

The reasons for regarding  $CuO \cdot H_2O$  as a hydrate, and for not placing  $AsO_3H_2$  in this class, are based on the chemical analogies of these compounds.  $CuO \cdot H_2O$  is very similar, in its methods of formation and properties, to compounds which are undoubtedly hydrated compounds.  $AsO_3H_2$  is an acid; the hydrogen of this compound can be replaced by certain metals; now acids as a class exhibit properties which undoubtedly show that they are not compounds of water.

Some compounds formed by the reaction of water with another compound are classed as hydrates, and some are not placed in this class. A compound may be formed by the union of water with another substance, and the compound may be resolved into water and the other substance, either by the action of heat or a dehydrating agent, and yet the compound in question is not necessarily placed among the hydrates. Water, for instance, reacts with  $N_2O_5$  to form nitric acid, and nitric acid loses water, forming  $N_2O_5$ , by reacting with  $P_2O_5$ ; yet nitric acid is not to be classed as a hydrate. Here again the properties and reactions of the compound formed by the reaction of water forbid us to regard it as a hydrate. The arguments against calling nitric acid a hydrate are not drawn solely from the reactions of this compound, but also from the general reactions of acids.

In discussing whether a specified compound is or is not a hydrate, regard must be paid to the chemical analogies of the compound, and to the reactions of compounds with which it is allied. Thus it is the custom to regard the compounds  $MO \cdot H_2O$ , where  $M = Ca, Sr, or Ba$ , as hydroxides rather than hydrates. One of the reasons for this is based on the undoubted similarities between these compounds and the compounds  $MOH$ , where  $M =$  an alkali metal. The latter compounds are certainly hydroxides; among

the reasons for this statement is the analogy in chemical reactions—e.g. reactions with acids and with  $\text{PCl}_5$ —between these compounds and the monohydric alcohols  $\text{C}_n\text{H}_{2n+1}\text{OH}$ . These alcohols cannot be called hydrates; they are not formed by the union of water with the hydrocarbons  $\text{C}_n\text{H}_{2n+2}$ ; they are produced by reactions between iodo-derivatives of the paraffins and  $\text{KOH}$ ; they react with  $\text{PCl}_5$  to form chloroparaffins  $\text{C}_n\text{H}_{2n+1}\text{Cl}$ . The compound formed by the reaction of  $\text{Na}_2\text{O}$  with  $\text{H}_2\text{O}$  may be formulated, so far as composition goes, as  $\text{Na}_2\text{O} \cdot \text{H}_2\text{O}$  or as  $\text{NaOH}$ . If the molecular weight were found to be 40, the formula  $\text{NaOH}$  would necessarily be adopted. In the absence of this evidence, we must have recourse to a study of the reactions of the compound. The weight of caustic soda which reacts with one molecular weight of hydrochloric acid ( $\text{HCl}$ ) is expressed by the number 40; the same number expresses the weight of this compound which reacts with one atom of sodium; hence we adopt 40 as the reacting weight of caustic soda; and hence we write the formula  $\text{NaOH}$  and not  $\text{Na}_2\text{O} \cdot \text{H}_2\text{O}$  (or  $\text{NaO} \cdot \text{H}_2$ ). One reason for writing the formula of caustic baryta  $\text{BaO} \cdot \text{H}_2$  and not  $\text{BaO} \cdot \text{H}_2\text{O}$  is found in the close analogies between this compound and caustic soda. Caustic baryta combines with water to form a compound  $\text{BaO} \cdot \text{H}_2 \cdot 8\text{H}_2\text{O}$ ; this compound is said to be a hydrated hydroxide; a hydrate, because  $8\text{H}_2\text{O}$  can be removed by heat; an hydroxide, for the reasons already given. A great mass of data regarding the dehydration of metallic hydroxides and hydrated oxides by heat is given in a paper by Carnelley a. Walker, *C. J.* 53, 59.

The specific volumes, or molecular volumes, of compounds formed by interaction of water with other compounds throw some light on the distinction between hydrates and hydroxides. The specific, or molecular, volume of a solid compound is defined as  $\frac{\text{formula-weight}}{\text{spec. grav.}}$ ; this

quotient may be represented by ( $V$ ). Clarke (*Am. S.* [3] 8, 428) has determined ( $V$ ) for a number of compounds formed by interactions of water with other compounds. He finds that for many hydrated chlorides the mean value of

$$\frac{(V)\text{MCl}_x \cdot x\text{H}_2\text{O} - (V)\text{MCl}_x}{x}$$

is 13.76; the maximum value being 15 and the minimum 12.5. In the chlorides examined  $M$  was  $\text{Ca}$ ,  $\text{Sr}$ ,  $\text{Ba}$ ,  $\text{Mg}$ ,  $\text{Cu}$ ,  $\text{Fe}$ , and  $\text{Co}$ ; and  $x$  varied from 2 to 6. Values for ( $V$ ) for the following compounds were also obtained:  $\text{B}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ,  $\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ ,  $\text{K}_2\text{O} \cdot \text{H}_2\text{O}$ ,  $\text{CaO} \cdot \text{H}_2\text{O}$ ,  $\text{SrO} \cdot \text{H}_2\text{O}$ ,  $\text{BaO} \cdot \text{H}_2\text{O}$ ,  $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ,  $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ,  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . Values were also obtained for ( $V$ ) for the oxides  $\text{B}_2\text{O}_3$ ,  $\text{I}_2\text{O}_5$ ,  $\text{K}_2\text{O}$ , &c. The difference

$$\frac{(V)\text{oxide} \cdot x\text{H}_2\text{O} - (V)\text{oxide}}{x}$$

varied from 7.4 to 19.4.

Hence it appears that the specific volume of each  $\text{H}_2\text{O}$  in hydrated chlorides has a mean value of about 18.76, and that in no case does the actual value differ much from this; but that no simple relation can be traced between ( $V$ ) for an oxide and ( $V$ ) for the product of the combination of that oxide with water in those cases in which we have reason to believe that a

rearrangement of the atoms of the molecule  $\text{H}_2\text{O}$  has taken place.

Perkin (*C. J.* 1886. 777) has used measurements of the magnetic rotatory powers of compounds (Mol. R.) to attempt a distinction between water of constitution and water of hydration. (Mol. R.) of water is taken as unity; if then (Mol. R.) of a compound is  $x$ , and if (Mol. R.) of the compound formed by adding water to this compound is increased by about 1 for each  $\text{H}_2\text{O}$  that has entered into combination, we may conclude that the new compound is a hydrate. The following examples are taken from Perkin's paper:—

- (Mol. R.) of  $\text{H} \cdot \text{CO} \cdot \text{H} = 1.671$ ;
- (Mol. R.) of  $\text{HCO} \cdot \text{H} \cdot \text{H} \cdot \text{O} = 1.676 + .995$ .
- (Mol. R.) of  $\text{CH}_3 \cdot \text{CO} \cdot \text{H} = 2.525$ ;
- (Mol. R.) of  $\text{CH}_3 \cdot \text{CO} \cdot \text{H} \cdot \text{H} \cdot \text{O} = 2.525 + 1.029$ .
- (Mol. R.) of many organic acids minus (Mol. R.) of the corresponding anhydride = c. .74.
- (Mol. R.) of  $\text{H}_2\text{SO}_4 = 2.315$ ;
- (Mol. R.) of  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O} = 2.315 + .873$ .
- (Mol. R.) of  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O} = 3.188$ ;
- (Mol. R.) of  $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O} = 3.188 + .925$ .
- (Mol. R.) of  $\text{CCl}_3 \cdot \text{CHO} = 6.591$ ;
- (Mol. R.) of  $\text{CCl}_3 \cdot \text{CHO} \cdot \text{H}_2\text{O} = 6.591 + .446$ .

The compounds formed by the union of formic and acetic acids with water appear to be hydrates. The compound formed by the union of sulphuric acid with water in the ratio  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  appears to be an hydroxide (Perkin thinks it may be  $\text{SO}(\text{OH})_2$ ), but the combination of more water with the compound thus produced is probably a process of hydration. Chloral hydrate is probably not a hydrate, but rather trichloro-ethylidene glycol  $\text{CCl}_3 \cdot \text{CH}(\text{OH})_2$ .

Differences can be traced between the various  $\text{H}_2\text{O}$  groups in some hydrated salts. Thus  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  loses  $4\text{H}_2\text{O}$  at about  $100^\circ$ , but the fifth  $\text{H}_2\text{O}$  only at c.  $220^\circ$ ;  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  at  $12.5^\circ$  loses  $5\text{H}_2\text{O}$ , at c.  $38^\circ$  the hydrate  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  remains, and complete dehydration occurs by heating towards redness. (Regarding the formation of different hydrates of the same salt from solutions v. Hammerl, *M.* 3, 419.) Thorpe and Watts (*C. J.* Trans. 1880. 109) have determined the specific volumes of various hydrated and dehydrated sulphates,  $\text{MSO}_4 \cdot x\text{H}_2\text{O}$ , where  $M = \text{Mg}$ ,  $\text{Zn}$ ,  $\text{Cu}$ ,  $\text{Mn}$ ,  $\text{Fe}$ ,  $\text{Co}$ , and  $x$  varied from 1 to 7. Putting ( $V$ )  $S$  as specific volume of the dry sulphate; they get the following results:—

Mean difference between	( $V$ ) $S$ and ( $V$ ) $S \cdot \text{H}_2\text{O} = 10.7$
" " "	( $V$ ) $S \cdot 2\text{H}_2\text{O} = 18.8$
" " "	( $V$ ) $S \cdot 3\text{H}_2\text{O} = 14.5$
" " "	( $V$ ) $S \cdot 4\text{H}_2\text{O} = 15.4$
" " "	( $V$ ) $S \cdot 7\text{H}_2\text{O} = 16.2$

Hence each  $\text{H}_2\text{O}$  group raises ( $V$ ) to a different extent.

Sodium phosphate crystallised from solution at the ordinary temperature has the composition  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ ; the crystals which separate at  $33^\circ$  are  $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$ ; there are also hydrates intermediate between these, and hydrate with less water than  $7\text{H}_2\text{O}$ . If one of these hydrates is heated in a closed space water is evolved and the pressure increases until at a certain pressure the change stops and equilibrium is produced. A study of the equilibrium pressures closes a marked difference between the hydrate

with 7 and 12 H<sub>2</sub>O. Debray (C. R. 66, 185) gives the following numbers:—

Temp.	Equilibrium pressures.	
	Salt with more than 7 and up to 12H <sub>2</sub> O	Salt with 7 or less than 7H <sub>2</sub> O
12.8°	7.4 mm.	4.8 mm.
16.8°	8.9 "	6.9 "
20.7°	14.1 "	9.4 "
24.9°	18.2 "	12.9 "
31.5°	30.2 "	21.3 "

It is evident that the distinction between hydrates and hydrazides is not one which can be rigidly drawn. One class of compounds shades off into the other. There is no means by using which we can refer any specified compound to this class or to that. Many reactions must be studied for each compound, and the classification finally adopted is generally only provisional.

M. M. P. M.

**HYDRAZIDES v. HYDRAZONES.** The phenyl-hydrazides of aldehydes and of ketones are described under the aldehydes and ketones from which they are prepared. Hydrazides are formed by elimination of water between an oxygenated body and a hydrazine. Elimination of water between an oxygenated body and an amine forms an amide or imide.

**HYDRAZIDO-BENZENE SULPHONIC ACID**  
v. PHENYL-HYDRAZINE SULPHONIC ACID.  
**HYDRAZIDO-BENZOIC ACID** v. PHENYL-HYDRAZINE CARBOXYLIC ACID.

**o-HYDRAZIDO-CINNAMIC ACID**  
NH<sub>2</sub>.NH.C<sub>6</sub>H<sub>4</sub>.CH.CH.CO<sub>2</sub>H. [171°]. From diazo-cinnamic acid by converting it first by Na<sub>2</sub>SO<sub>3</sub> into SO<sub>2</sub>Na.N<sub>2</sub>O.H<sub>2</sub>.CH.CH.CO<sub>2</sub>H, then reducing by hydrochloric acid and zinc-dust to SO<sub>2</sub>Na.NH.NH.C<sub>6</sub>H<sub>4</sub>.CH.CH.CO<sub>2</sub>H, and finally decomposing this by HCl gas (Fischer a. Kuzel, A. 221, 276; A. 227, 303). Yellowish crystals. Nearly insol. water, alcohol, ether, benzene, or light petroleum. Sol. alkalis and acids. Its acetic acid solution bleaches litmus and indigo (unlike the simpler hydrazines), reduces alkaline copper solution, and ammoniacal silver solution. When melted it forms indazole (q. v.).

Salt.—HAHCl: [146°]; yellowish crystalline powder, soluble in alkalis, reduces Fehling's solution in the cold. Heat changes it to indazole (q. v.), not into its anhydride.

**Anhydride** v. AMIDO-CARBOSTYRIL.

**o-HYDRAZIDO-PHENOL.**

**Methyl ether** C<sub>6</sub>H<sub>4</sub>(OMe).NH.NH<sub>2</sub>. [48°]. **Methoxy-phenyl-hydrazine.** From C<sub>6</sub>H<sub>4</sub>(OMe).NH.NH.SO<sub>2</sub>H and conc. HCl (Reisenegger, A. 221, 819). Slender white needles, which turn brown in air. Insol. water, v. sol. alcohol, ether, and benzene. Reduces Fehling's solution, H<sub>2</sub>O, and ammoniacal AgNO<sub>3</sub>. With cyanic ether it forms a urea (semicarbazide) MeO.C<sub>6</sub>H<sub>4</sub>.N.N<sub>2</sub>.CO.NHET [110°] needles.

Salts.—BHCl.—B<sub>2</sub>H<sub>2</sub>CO<sub>2</sub>.—H<sub>2</sub>C<sub>2</sub>H<sub>2</sub>(NO<sub>2</sub>)<sub>2</sub>OH.

**Acetyl derivative** C<sub>6</sub>H<sub>4</sub>(OMe).N<sub>2</sub>H<sub>2</sub>.Ac: [125°]; needles.

**o-HYDRAZIDO-PHENOL'-s-SULPHONIC ACID.**

Salt.—HO.C<sub>6</sub>H<sub>4</sub>.NH.NH.SO<sub>2</sub>K. From HO.C<sub>6</sub>H<sub>4</sub>.N<sub>2</sub>.SO<sub>2</sub>K, zinc-dust and glacial HOAc (Reisenegger, A. 221, 815). White plates. Quickly turns red when moist. V. sol. water,

the solution being very unstable. Reduces Fehling's solution.

**Methyl derivative**

MeO.C<sub>6</sub>H<sub>4</sub>.NH.NH.SO<sub>2</sub>H.

Salt.—NaA<sup>aq</sup>. From C<sub>6</sub>H<sub>4</sub>(OMe).NH<sub>2</sub> by diazotisation and treatment with Na<sub>2</sub>SO<sub>3</sub> (R.). Plates. Reduces cold Fehling's solution. Warmed with conc. HCl it forms o-hydrazido-phenol methyl ether (q. v.).

**p-Hydrazido-phenol-s-sulphonic acid.**

Salt.—HO.C<sub>6</sub>H<sub>4</sub>.NH.NH.SO<sub>2</sub>K. Prepared in a similar way from the p-compound (R.). White scales, more stable than the o-compound. Reduces cold Fehling's solution.

**o-HYDRAZIDO-β-PHENYL-PROPIONIC ACID.**

Sodium salt.—

NH<sub>2</sub>.NH.C<sub>6</sub>H<sub>4</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>Na (E. Fischer a. Kuzel, A. 221, 282). This salt may be got by reducing C<sub>6</sub>H<sub>4</sub>(NH.NH.SO<sub>2</sub>Na).CH<sub>2</sub>.CH.CO<sub>2</sub>H by sodium amalgam in alkaline solution. Precipitated by adding NaCl and acetic acid. Small crystals, v. sol. water. HCl liberates the acid which at once changes into its anhydride, amido-hydrocarbostyryl (q. v.) [143°].

**Ethyl-hydrazido-phenyl-propionate acid** C<sub>6</sub>H<sub>4</sub>(NH.NH<sub>2</sub>).CH<sub>2</sub>.CH.CO<sub>2</sub>H. **Ethyl-hydrazine-hydrocinnamic acid.** Formed by reduction of the nitrosamine of ethyl-o-amido-phenyl-propionic acid by zinc-dust and glacial acetic acid (E. Fischer a. Kuzel, A. 221, 294; B. 16, 1451). Reduces Fehling's solution on warming. Evaporated with glacial acetic acid it changes to ethyl-hydro-carbazo-styryl.

Salts.—BA<sup>aq</sup>: crystals.—HAHCl. [146°]. At 160° it gives off HCl and H<sub>2</sub>O becoming ethyl-hydro-carbazo-styryl.

**Anhydride** C<sub>6</sub>H<sub>4</sub><CH<sub>2</sub>.CH<sub>2</sub>>CO. **Ethyl-hydro-carbazo-styryl.** [165.5°]. Long white needles, sl. sol. water, v. sol. alcohol and ether. Insol. alkalis, may be distilled unchanged. Warmed with HCl it changes back to the ethyl-hydrazido-phenyl-propionic acid, differing in this respect from hydrocarbostyryl which is not changed by hot HCl.

**Isomeride of the anhydride.**

C<sub>6</sub>H<sub>4</sub><CH<sub>2</sub>.CH<sub>2</sub>>CO. **Oxy-ethyl-amido-quinoline-dihydride.** [74°]. Formed by heating the anhydride of o-hydrazido-cinnamic acid with alcohol and EtI at 100° (F. a. K.). Crystals, v. sol. alcohol, sl. sol. water. Gives a nitrosamine.

**HYDRAZIDO-TOLUENE SULPHONIC ACID**  
v. TOLYL-HYDRAZINE SULPHONIC ACID.

**HYDRAZIMIDO-COMPOUNDS** v. o-AMIDO-AZO-COMPOUNDS, vol. i. p. 870.

**HYDRAZINE** N<sub>2</sub>H<sub>4</sub>, i.e. NH<sub>2</sub>.NH<sub>2</sub>. **Di-amidogen.** Formed by treating diazo-acetic ether with hot conc. KOH, decomposing the resulting crystalline potassium salt by HCl, and digesting the yellow crystalline acid so liberated with very dilute sulphuric acid. No gas is evolved, but the solution becomes colourless, and hydrazine sulphate separates on cooling (Ourtins, B. 20, 1632). Hydrazine sulphate is best obtained by warming tri-azo-acetic acid (250 g. in 2 litres of water) with H<sub>2</sub>SO<sub>4</sub> (800 g.) until effervescence ceases. Further quantities may be obtained from the mother-liquor after hydrazine sulphate

has crystallised out, by shaking with benzoic aldehyde, and decomposing the resulting crystalline compound with dilute sulphuric acid (Curtius a. Jay, *J. pr.* [2] 89, 27). Hydrazine is only known in its salts and in the form of a hydrate  $N_2H_4 \cdot H_2O$  which is got by heating the hydrochloride in a silver tube with quick lime. This hydrate is a fuming liquid (119°), with very slight odour. It corrodes glass, attacks cork and india-rubber, and has an alkaline and burning taste. Hydrazine reduces Fehling's solution and ammoniacal  $AgNO_3$  in the cold. With  $CuSO_4$  it gives a thick red pp. of  $Cu_2O$ ; with  $HgCl_2$  a white pp. of calomel; with alum a pp. of alumina. With aromatic aldehydes and ketones it gives sparingly soluble crystalline compounds. Nitrites decompose its salts with evolution of gas.

**Salts.**— $N_2H_4 \cdot H_2SO_4$ : tables; sl. sol. cold, v. sol. hot, water; insol. alcohol. Not decomposed by heating to 250°; but at a higher temperature it decomposes with explosive evolution of gas, liberating sulphur— $N_2H_4 \cdot H_2Cl_2$ . [198°]. From the preceding and  $BaCl_2$ . Large regular crystals; v. sol. cold water, m. sol. alcohol.  $PtCl_4$  decomposes it with evolution of gas.— $BHCl$ : [89°]; long white needles (from hot alcohol). Decomposed at 240° into  $NH_4Cl$ , water, and nitrogen, v. sol. water.—Formate  $B''(H_2CO_2)$ : [128°]; got by heating triazo-acetic acid with water. Rectangular tables.

**Di-benzylidene hydrazine**  $N_2(CHPh)_2$ . [93°]. From hydrazine sulphate and benzoic aldehyde. Long lustrous yellow prisms; insol. water, sol. hot alcohol. Decomposed by heat into nitrogen and  $PhCH:CHPh$ , a by-product being  $N_2(CHPh)_2$ . [78°]. The molecular weight of di-benzylidene-hydrazine has been confirmed by Raoult's method.

**Di-benzyl hydrazine**  $N_2H_4(CH_2Ph)_2$ . Formed by reducing the preceding with sodium-amalgam. Its hydrochloride  $BHCl$  [140°] crystallises from alcohol in small lustrous tables, v. sol. water.

**Di-oxy-di-benzylidene-hydrazine**  $N_2(CH_2OCH_2Ph)_2$ . [205°]. From salicylic aldehyde and salts of hydrazine. Tables, insol. water and cold alcohol.

**Di-nitro-di-benzylidene hydrazine**  $N_2(CH_2OCH_2NO_2)_2$ . [181°]. From o-nitro-benzoic aldehyde and salts of hydrazine. Groups of bright yellow needles.

**Di-cinnamylidene-hydrazine**  $N_2(CH_2CH:CHPh)_2$ . [162°]. From cinnamic aldehyde and hydrazine salts. Yellow tables.

**HYDRAZINES.** The name 'hydrazine' was applied by Emil Fischer to the then hypothetical diamidogen  $H_2N.NH_2$ , which he regarded as the parent substance of the *hydrazines*, a large and important class of bases discovered by him, derived from diamidogen by the replacement of either one or two atoms of hydrogen by monad hydrocarbon radicles. The name was intended to indicate the connection of these bases with the azo- and diazo-compounds, and in particular with hydrazobenzene  $C_6H_5.NH.NH.C_6H_5$  (symmetrical diphenylhydrazine), the oldest known member of the class of the hydrazines, whilst at the same time the termination 'azine' was formed on the analogy of 'amine', in order that a parallel nomenclature might be employed in the case of corresponding derivatives of the hydrazines and amines; thus the *hydrazonium*

compounds would correspond with the *ammonium* compounds (A. 190, 70).

Hydrazine itself has recently been prepared by Curtius, and the analogy between its reactions and those of the compounds discovered by Fischer fully justifies the foregoing classification.

The hydrazines are divided into primary and secondary, according as one or two hydrogen atoms in the original diamidogen molecule have been replaced by hydrocarbon radicles. If the two radicles are attached to different nitrogen atoms the resulting secondary hydrazine is termed *symmetrical*; if to the same nitrogen atom it is *unsymmetrical*. The unsymmetrical secondary hydrazines behave like tertiary amines; they unite with the alkyl halogenides to form *hydrazonium* compounds:

**Preparation.**—Hydrazine  $NH_2.NH_2$  is formed, together with oxalic acid, when tri-azo-acetic acid is warmed with water or with mineral acids:

It is as yet known only in the form of its salts and of its hydrate  $N_2H_4 \cdot H_2O$  (Curtius a. Jay, *J. pr.* [2] 39, 27).

The derivatives containing alkyl and other radicles are obtained by reactions which have no analogy with the foregoing.

**Primary hydrazines.**—1. The primary hydrazines, of which phenyl-hydrazine  $NHPh.NH_2$  may be taken as a type, are most simply obtained by reducing diazo-salts with stannous chloride:

(V. Meyer a. Lecco, B. 16, 2976).—2. The method originally employed by E. Fischer (A. 190, 71), in which sodium sulphite is used as a reducing agent, is more complicated. It gives in some cases a better yield, although occasionally the reverse is the case (B. 17, 572). In the first stage of the reaction the diazo-salt is converted by the sodium sulphite into a diazo-sulphonate:

Hydrochloric acid is then added, which decomposes another molecule of sodium sulphite, and the liberated sulphurous acid or acid sulphite reduces the reddish-yellow sodium diazo-sulphonate to the colourless sodium phenylhydrazine-sulphonate:

Zinc-dust and acetic acid are added to complete the reduction, and the sodium hydrazine-sulphonate is then hydrolysed by heating it with concentrated hydrochloric acid, when it yields phenylhydrazine hydrochloride:

from which the base can be liberated by caustic alkali (E. Fischer, A. 190, 78).—3. When a diazo-amido-compound is treated in alcoholic solution with zinc-dust and acetic acid the diazo-group is reduced and the corresponding hydrazine is formed together with an amine:

This method is not of practical importance (H

soher, A. 190, 77).—4. The primary hydrazines retaining alkyl radicals cannot be obtained by the foregoing reactions, as the diazo-derivatives of the alkyls are unknown. They may, however, be prepared from the nitroso-alkyl-ureas. Thus when nitroso-di-ethyl-urea is reduced with zinc-dust and acetic acid the nitroso-group is converted into an amido-group:

his amido-compound is then hydrolysed by heating with fuming hydrochloric acid, when it yields ethylhydrazine and ethylamine:

**Secondary hydrazines.**—1. The unsymmetrical secondary hydrazines, both in the fatty and in the benzene series, may be obtained by the reduction of the nitrosamines with acetic acid and zinc-dust:

(E. Fischer, A. 190, 146).—2. The unsymmetrical secondary hydrazines are formed, along with the isomeric symmetrical compounds, by the action of the alkyl halogenides on the primary hydrazines; thus phenylhydrazine yields with ethyl bromide the compounds NPhEt.NH<sub>2</sub> and NPhH.NEtH (E. Fischer a. Ehrhard, A. 199, 825). By employing in this reaction sodium-phenylhydrazine N<sup>1</sup>PhNa.NH<sub>2</sub>, instead of free phenylhydrazine, only the unsymmetrical compound is formed:

(Michaelis, B. 19, 2450; Phillips, B. 20, 2485). The unsymmetrical secondary hydrazines formed by alkylation are identical with those obtained by the reduction of the corresponding nitrosamines.

**Properties.**—The fatty hydrazines are liquids boiling without decomposition; those of the benzene series are either solids of low melting-point or oily liquids, and boil with partial decomposition. Hydrazine itself and some of the fatty hydrazines are diacid bases; others are monacid; the hydrazines of the benzene series are all monacid bases.

**Reactions.**—1. The hydrazines are very stable towards reducing agents, but are readily attacked by oxidising agents. Thus the primary hydrazines reduce Fehling's solution in the cold, the secondary on warming. By shaking with mercuric oxide the salts of the primary hydrazines are oxidised to diazo-salts; this is most readily shown with potassium phenylhydrazine-sulphonate Ph.NH.NH.SO<sub>3</sub>K, which is thus converted into the diazobenzene-sulphonate Ph.N<sub>2</sub>.N.SO<sub>3</sub>K (E. Fischer, A. 190, 97). The unsymmetrical secondary hydrazines are converted by mercuric oxide into tetrazones:

(F., A. 190, 167), whilst the symmetrical secondary hydrazines are oxidised to azo-compounds:

(E. Fischer a. Ehrhard, A. 199, 828).—2. Nitrous acid converts the primary hydrazines into ni-

troso-compounds; thus with phenylhydrazine Ph.NH.NH<sub>2</sub> + HNO<sub>2</sub> = Ph.N(NO).NH<sub>2</sub> + H<sub>2</sub>O, and when the nitroso-compound thus formed is treated with dilute alkalis it yields diazo-benzenimide:

(F., A. 190, 89). The unsymmetrical secondary hydrazines, on the other hand, when treated with nitrous acid, are converted with evolution of nitrous oxide into the nitrosamines from which they were obtained: NPhMe.NH<sub>2</sub> + 2HNO<sub>2</sub> = NPhMe.NO + N<sub>2</sub>O + 2H<sub>2</sub>O (F., A. 190, 159).—3. With the alkyl halogenides the primary hydrazines yield a mixture of symmetrical and unsymmetrical secondary hydrazines, whereas sodium-phenylhydrazine gives only the unsymmetrical compound (v. supra). The unsymmetrical secondary hydrazines unite directly with an alkyl bromide or iodide to form a hydrazonium compound:

That triethylhydrazonium iodide has the foregoing constitution is shown by its behaviour on reduction with zinc-dust and dilute sulphuric acid, when it yields triethylamine, ammonia, and hydriodic acid:

(E. Fischer a. Ehrhard, A. 199, 316-18).—4. By the action of acidoyl chlorides on the primary hydrazines mono- and di-acidoyl derivatives are obtained. Phenylhydrazine yields, by the limited action of benzoyl chloride, symmetrical benzoyl-phenylhydrazine Ph.NH.NH.CO.Ph, which by oxidation in chloroform solution with mercuric oxide is converted into benzoyl-diazo-benzene Ph.N<sub>2</sub>.N.CO.Ph (E. F., A. 190, 125). By acting with benzoyl chloride on sodium-phenylhydrazine Ph.CO.NPh.NH<sub>2</sub> is obtained (Michaelis a. Schmidt, B. 20, 1713). Both these mono-benzoylphenylhydrazines, when treated with benzoyl chloride, yield the same dibenzoyl-phenylhydrazine, which has therefore the constitution Ph.CO.NPh.NH.CO.Ph (E. F., A. 190, 128; M. a. S., l.c.). These acidoyl-derivatives of the hydrazines are the hydrazides of the acids and correspond with the amides, anilides, &c.<sup>1</sup> Thus:

"A large number of similar derivatives corresponding with the amides and alkyl-amides have been prepared; thus phenylhydrazine hydrochloride reacts with potassium cyanate to form phenylsemicarbaside Ph.NH.NH.CO.NH<sub>2</sub> (the semi-urea of phenylhydrazine); phenylhydrazine unites with carbon dioxide yielding as product phenylhydrazine phenylcarbasate Ph.NH.NH.CO.O.N<sub>2</sub>H.Ph, and with carbon disulphide to form phenylhydrazine phenylthiocarbasate Ph.NH.NH.CO.S.N<sub>2</sub>H.Ph (corresponding respectively with ammonium carbamate and ammonium thio-carbamate), and on heating the

<sup>1</sup> It is, therefore, inaccurate to apply the name 'hydrazides' to the 'hydrazones' (p. 4.).

latter compound it yields the thio-urea *diphenyl-thiocarbamide*  $\text{CS}(\text{NH}.\text{NHPH})_2$  (E. F., A. 190, 118-119). In like manner *azidines* are known, corresponding with the amidines; thus *benzethyldiphenylazidine*  $\text{Ph}.\text{C} \begin{smallmatrix} \text{N}.\text{NHPH} \\ \text{N}.\text{NHPH} \end{smallmatrix}$  (Pinner, B. 17, 182).—5. Phenylhydrazine unites directly with *cyanogen* to form *dicyano-phenylhydrazine* (F.).—6. One of the most important reactions of the hydrazines is that in which they undergo condensation with compounds containing *carbonyl-groups*: thus

In this way phenylhydrazine may, like hydroxylamine, be employed in testing for the presence of carbonyl-groups in compounds (E. Fischer, A. 190, 184; B. 17, 572). The compounds thus formed are known as *hydrazones* (q. v.). The reaction is occasionally complicated by the presence of other reactive groups, in addition to the carbonyl group, in the molecule of the compound acted upon by phenylhydrazine; thus although compounds containing the *α-ketone-alcohol group*  $-\text{CH}(\text{OH}).\text{CO}-$  react in the cold with only one mol. of phenyl hydrazine to form colourless compounds containing the group  $-\text{CH}(\text{OH}).\text{C}(\text{N}.\text{NHPH})-$ , yet when the compound thus formed is heated with excess of phenylhydrazine, the alcohol group undergoes dehydration, reacting at the same time with a second mol. of phenylhydrazine and giving rise to a yellow compound containing the complex  $-\text{C}(\text{N}.\text{NHPH}).\text{C}(\text{N}.\text{NHPH})-$ . Such compounds in which two hydrazine-residues are attached to contiguous carbon atoms are known as *osazones* (v. HYDRAZONES) and may also be obtained directly by the action of the hydrazines on the *α-diketones*. They are of great importance in connection with the carbohydrates, which may frequently be recognised by means of their characteristic osazones (E. Fischer, B. 17, 579; 20, 821). Again, an unsaturated hydrocarbon group, if contiguous to the carbonyl-group, may also take part in the reaction with phenylhydrazine:

(E. Fischer a. Knövenagel, A. 239, 194; v. also Knorr a. Blank, A. 239, 139). An analogous case is that of ethylic aceto-acetate which reacts with phenylhydrazine in the cold with elimination of water to form the hydrazones

but on heating this compound, it parts with alcohol yielding a phenylpyrazolone of the formula

the carbethoxyl-group also taking part in the reaction (Knorr, A. 238, 146). Similar complex condensations have been described with *β-diketones* and with some *γ-diketones* (E. Fischer a. Bülow, B. 18, 2135; Paal, B. 17, 914; Japp a. Huntly, C. J. 1888, 184).

Various other reactions of hydrazines are known, and some of these are doubtless of general application, although they have as yet been applied only in special cases. They will be described under the appropriate hydrazines.

F. R. J.

#### HYDRAZO-BENZENE v. s-DI-PHENYL-HYDRAZINE.

HYDRAZO-BENZOIC ACID v. DI-PHENYL-HYDRAZINE v. CARBOXYLIC ACID.

HYDRAZO-COMPOUNDS. Symmetrical derivatives of hydrazine, of the formula  $\text{RNH}.\text{NHR}'$  where R and R' represent radicles attached by means of carbon to the two atoms of nitrogen (cf. HYDRAZINES and s-DI-PHENYL-HYDRAZINE). They are described in this dictionary as derivatives of hydrazine.

HYDRAZO-HYDROQUINONE v. TETRA-OXY-DI-PHENYL-HYDRAZINE.

HYDRAZO-DI-METHYL-HYDROQUINONE v. Tetra-methyl derivative of TETRA-OXY-DI-PHENYL-HYDRAZINE.

HYDRAZO-NAPHTHALENE v. DI-NAPHTHYL-HYDRAZINE.

HYDRAZONES. The compounds formed by the condensation of substances containing the carbonyl group with phenylhydrazine were named by many chemists 'phenylhydrazides,' or more shortly, 'hydrazides.' E. Fischer, however (B. 21, 984), has pointed out the impropriety of the term. A 'hydrazide' corresponds with an 'amide'; the phenylhydrazido-group is  $\text{Ph}.\text{N}.\text{H}_2$ ; thus the phenylhydrazide of benzoic acid is  $\text{Ph}.\text{CO}.\text{N}.\text{H}.\text{Ph}$ . In order to avoid the ambiguity which the above erroneous use of this term introduces, Fischer has proposed to name the compounds in which the dyad group  $\text{NPh}.\text{H}.\text{N}=\text{}$  replaces the oxygen of a carbonyl group 'phenylhydrazones'—the termination *one* serving to suggest their connection with ketones or with carbonyl compounds generally. Further, as in the very great majority of cases it is *phenylhydrazine* which is employed in the preparation of these compounds, the abbreviated form 'hydrazone' may be applied in all such cases, and is to be taken to signify 'phenylhydrazone' unless the contrary is stated. The name 'osazone' is, for reasons to be explained later, applied to any compound containing two dyad groups  $\text{NPh}.\text{H}.\text{N}=\text{}$  attached to two contiguous carbon atoms. Thus in the case of the two compounds obtained from glyoxal and phenylhydrazine we have:

(E. Fischer, l.c.).

Formation.—The fact that phenylhydrazine reacts with aldehydes was first pointed out

R. Fischer (A. 190, 184); thus with benzaldehyde:

Later (B. 16, 661, footnote; 17, 572) he extended the reaction to ketones, diketones, ketonic acids, and carbonyl compounds generally, and proposed the use of phenylhydrazine as a reagent, analogous in its action to hydroxylamine, to be used in testing for the presence of carbonyl groups in compounds. At first (B. 17, 578) he recommended that the compound to be investigated should be heated with an aqueous solution of phenylhydrazine hydrochloride mixed with excess of sodium acetate, to which alcohol might be added to dissolve the compound; but later (B. 22, 90, footnote) a mixture of equal volumes of free phenylhydrazine and 50 p.c. acetic acid was substituted. The hydrazone generally separates as a sparingly soluble and frequently crystalline compound. The formation of a hydrazone under these circumstances is a proof that the compound under examination contains at least one carbonyl group in the ketonic or aldehydic form, i.e. attached with both its affinities to carbon atoms, or to a carbon and a hydrogen atom, or to two hydrogen atoms. Carbonyl groups attached with one or both affinities to oxygen or to nitrogen—as in  $\text{CO.OH}$ ,  $\text{CO.NH}_2$ , &c.—do not react with phenylhydrazine. In some respects phenylhydrazine is to be preferred as a reagent to hydroxylamine: it is more readily obtained, and compounds containing more than one carbonyl group frequently react with two mols. of phenylhydrazine, thus showing the presence of two carbonyl groups, when they would only react with one mol. of hydroxylamine. \*The hydrazones of monocarbonyl compounds are formed like the aldehydrazones already mentioned: thus, *acetonehydrazone*  $(\text{CH}_3)_2\text{C}(\text{N.HPh}).\text{COOH}$ , and *phenylhydrazonopyruvic acid*  $\text{CH}_3.\text{C}(\text{N.HPh}).\text{COOH}$ . The action of phenylhydrazine on dicarbonyl compounds, however, varies with the relative positions of the two carbonyl groups. \*  $\alpha$ -Dicarbonyl compounds, in which the two carbonyl groups are directly united, react either with one or with two mols. of phenylhydrazine, according to the proportions employed, to form respectively hydrazones and osazones; thus, diacetyl  $\text{CH}_3.\text{CO.CO.CH}_3$  yields *diacetylmonohydrazone*  $\text{CH}_3.\text{C}(\text{N.HPh}).\text{CO.CH}_3$  and *diacetyllosazone*  $\text{CH}_3.\text{C}(\text{N.HPh}).\text{C}(\text{N.HPh}).\text{CH}_3$  (v. Peckmann, B. 21, 1418). Glyoxal and benzil form similar osazones (Pickel, A. 232, 280).  $\beta$ -Dicarbonyl compounds, in which the two carbonyl groups are separated by a carbon atom, react with one mol. of phenylhydrazine to form an unstable hydrazone, which spontaneously parts with water yielding a pyrazole:

\* Abbreviation for "benzaldehyde-hydrazone," like "benzaloxim" for "benzaldehyde-oxim."

however, occur with  $\beta$ -diketones of the form  $-\text{CO.CR}'_2.\text{CO}-$ , in which both hydrogen atoms of the methylene group are replaced by alkyls (Fischer a. Bülow, B. 18, 2185; Knorr, A. 238, 139).  $\gamma$ -Dicarbonyl compounds, in which the two carbonyl groups are separated by two carbon atoms, react sometimes with 2 mols. of phenylhydrazine to form dihydrazones, thus:

Acetonyl-acetone

Acetonyl-acetophenone

The constitution of the compounds of the latter class is unknown (Paal, B. 17, 914).

Allusion has already been made to the similarity in the action of phenylhydrazine and of hydroxylamine on carbonyl compounds. The phenylhydrazone group  $\text{N.HPh}$  corresponds with the hydroximido-group  $\text{N.OH}$ . V. Meyer has shown that hydroximido-(isonitroso)-compounds are also formed by the action of nitrous acid on compounds containing the group  $\text{CH}_2$  or  $\text{CHR}'$  attached to two electro-negative radicles, R' being a readily displaceable radicle (acetyl or carbonyl). Japp and Klingemann (C. J. 1888, 528; B. 20, 3284 and 3898; 21, 549) have found that by the action of diazo-salts on compounds which yield hydroximido-compounds with nitrous acid (or on their sodium compounds) hydrazones are formed. The following equations, in which for the sake of simplicity free diazobenzene is employed instead of a diazo-salt, will illustrate the analogy between the action of nitrous acid and diazo-salts on compounds of the above-mentioned type.

Thus with ethylic aceto-acetate the reactions may be expressed as follows:

Ethylic hydroximido-aceto-glyoxylate

Diazobenzene

Ethylic phenylhydrazonaceto-glyoxylate

In the case of monalkyl derivatives of ethylic aceto-acetate, the acetyl group is expelled:

Ethylic hydroximido-pyruvate

Ethylic phenylhydrazonopyruvate

With free aceto-acetic acid, or monalkyl aceto-acetic acids, the carboxyl group is eliminated instead of the acetyl group:

Pyruvaldehydoxime

Pyruvaldehydrazone

\* Beyer and Glaisen have, however, shown that in certain cases  $\gamma$ -diketones are formed (B. 21, 1697).

whilst methaceto-acetic acid reacts with diazobenzene forming the monohydrazones of di-acetyl  $\text{CH}_3\text{CO.C}(\text{N}_2\text{HPh}).\text{CH}_3$  (v. *supra*) and ethaceto-acetic acid yields the corresponding compound of the formula  $\text{CH}_3\text{CO.C}(\text{N}_2\text{HPh}).\text{C}_2\text{H}_5$ . Those of the foregoing hydrazones which contain a carbonyl group contiguous to the phenylhydrazone group may be made to react with phenylhydrazine to form osazones (J. A. K., *l.c.*).

Phenylhydrazine is capable of expelling the hydroximido-group to form hydrazones:

(Just, B. 19, 1206).

**Properties.**—A few of the hydrazones are liquid, but the majority are crystalline solids. By warming the solution of a carbonyl compound with phenylhydrazine and determining the melting-point of the hydrazone formed, the hydrazone, and thus the carbonyl compound from which it is derived, may frequently be identified. Many of the hydrazones decompose on melting; in determining the melting-point, therefore, the temperature must be raised as rapidly as is consistent with accuracy, otherwise too low a melting-point will be found (E. Fischer, B. 17, 573; 20, 527).

**Reactions.**—1. The hydrazones are readily reduced either with sodium amalgam and acetic acid or with zinc-dust and acetic acid. According to the length to which the reduction is carried the hydrazone either takes up two or four atoms of hydrogen—in the latter case with disruption of the molecule at the point of union of the nitrogen atoms. Thus phenylhydrazone-pyruvic acid  $\text{CH}_3\text{C}(\text{N.NHPh}).\text{COOH}$  yields in the first stage of reduction benzene-hydrazopropionic acid  $\text{CH}_3\text{CH}(\text{NH.NHPh}).\text{COOH}$  (E. Fischer, A. Jourdan, B. 16, 2243), and this by farther reduction breaks up into alanine  $\text{CH}_3\text{CH}(\text{NH}_2).\text{COOH}$  and aniline (Japp & Klingemann, C. J. 1888, 585). This latter mode of reduction into a mixture of two bases was discovered by Tafel (B. 19, 1924), who proposed to employ the reaction as a method of preparing primary amines from carbonyl compounds; thus benzaldehyde could be converted, by the reduction of its hydrazone, into benzylamine.—2. The action of heat on the hydrazones has not been much studied. Many of them decompose when heated, yielding amongst other products aniline. When aldehydehydrazone is heated for some time to boiling it is partially converted into diacetyl-osazone (v. *supra*):

(Japp & Klingemann, C. J. 1888, 542).—3. By the action of sodium and an alkyl halogenide on a hydrazone (Phillips, B. 20, 2487), an alkyl group may be introduced; thus with benzaldehydehydrazone:

and as the compound resulting in this case is identical with that obtained by the action of benzaldehyde on unsymmetrical benzyl-phenylhydrazine, it is thus proved that the hydrazones have the constitution  $\text{R}^1\text{CH:N.NHPh}$  and not, as was otherwise conceivable, the constitution

may be substituted for sodium in the above reactions (Landsberg, C. J. 1888, 519).—4. By heating a hydrazone with an anhydride of an organic acid an acidoyl group may be introduced; thus, benzaldehydehydrazone, when heated with acetic anhydride, yields the compound  $\text{Ph.C:N.N}(\text{C}_2\text{H}_5\text{O})\text{Ph}$  (Michaelis and Schmidt, B. 20, 1717 n.).—5. By heating hydrazones with mineral acids they may generally be hydrolysed into the carbonyl compound and hydrazine from which they are derived (E. Fischer, A. 190, 135). The hydrazones of  $\alpha$ -ketonic acids, however—thus, of pyruvic acid—are not hydrolysed by dilute mineral acids, whilst with strong acids they undergo complex decomposition (E. Fischer & Jourdan, B. 16, 2243). Some secondary hydrazones are converted by hydrochloric acid into indole derivatives, ammonia being eliminated in the process:

(E. Fischer & Jourdan, B. 16, 2249; E. Fischer, A. 236, 116).—6. If a phenylhydrazone contain a methyl- or a methylene-group directly attached to the carbon atom of the original carbonyl-group, it may generally be converted into an indole-derivative by heating with zinc chloride. The reaction occurs with elimination of ammonia, and resembles the foregoing formation of an indole-derivative by the action of hydrochloric acid, but is applicable to primary as well as to secondary hydrazones:

(E. Fischer, A. 236, 116). Aldehydehydrazone, however, when heated with zinc chloride, does not yield indole, but its homologues are converted into homologues of indole.

Some hydrazones undergo specific chemical changes, not general to the class, but depending on the presence of certain reactive groups in the molecule of the particular hydrazone. Such changes are, for example, the formation of pyrazolone from the hydrazone of ethyl aceto-acetate and of pyrazolines from the hydrazones of unsaturated carbonyl compounds (v. HYDRAZINES).

**Osazones.** As already mentioned, the name osazone denotes a compound containing in its molecule two dyad groups  $\text{NPh.N} \begin{array}{c} \diagup \text{C} \\ \diagdown \text{C} \end{array}$  attached to two contiguous carbon atoms. E. Fischer (B. 17, 579) obtained from carbohydrates a series of characteristic compounds formed by the introduction of two phenylhydrazones group

## HYDRAZONES.

into the molecule of a carbohydrate (*v. infra*). The compound from dextrose was termed *phenyl-glucosazone*; that from galactose, *phenyl-galactosazone*, and so on. Later, when it was found that in these compounds the two phenylhydrazine residues were in contiguous positions, the name *osazones* was applied to all compounds containing this particular grouping (E. Fischer, B. 21, 985).

Various methods for the preparation of osazones have already been incidentally mentioned in the course of this article. Thus, they are formed (1) by the action of 2 mols. of phenylhydrazine on an  $\alpha$ -dicarbonyl compound; (2) by the action of 1 mol. of phenylhydrazine on a hydrazone containing a carbonyl-group contiguous to the hydrazone-group, such hydrazones being formed as intermediate products in the first-mentioned reaction; and (3) by heating an aldehydrazone. In addition to their formation by the foregoing reactions, which have been already described, osazones may be obtained (4) by heating iso-nitroso-ketones, in which the iso-nitroso-group is contiguous to the carbonyl-group, with phenyl-hydrazine:

(*v. Pechmann, B. 20, 2543*). They are also formed (5) by the action of phenylhydrazine on compounds containing the group  $-\text{CH}(\text{OH})\cdot\text{CO}-$ , thus, on  $\alpha$ -ketone-alcohols and  $\alpha$ -aldehyde-alcohols; and it is the members of the carbohydrate family belonging to these classes which yield osazones. In the cold—unless on long standing—only the carbonyl-group reacts with phenylhydrazine, and a hydrazone containing the group  $-\text{CH}(\text{OH})\cdot\text{C}(\text{N}\cdot\text{HPh})-$  is formed; but this compound, on heating with excess of phenylhydrazine, is converted into an osazone, the alcohol-group also taking part in the reaction. The mol. of hydrogen which is removed in this process reduces a mol. of phenylhydrazine to aniline and ammonia:

(E. Fischer, B. 17, 579; 20, 821; 21, 988, 2631).  $\alpha$ -Dicarbonyl compounds, on the other hand, react with excess of phenylhydrazine to form osazones even in the cold.

The osazones are of a yellow colour: the yellow colouring matters known as 'tartrazines' are the osazones of dihydroxytartaric acid. Conc. sulphuric acid dissolves the various osazones, giving characteristic colourations, and the solution generally exhibits some definite colour-change on standing (Japp & Klingemann, B. 21, 549). Fuming hydrochloric acid hydrolyses the osazones in the cold into phenylhydrazine and the  $\alpha$ -dicarbonyl compound from which they are derived (E. Fischer, B. 21, 381).

**Osotriazones.** The osotriazones contain the closed-chain complex  $\begin{array}{c} \text{—O—N—} \\ | \quad \diagup \\ \text{—O—N—} \end{array}$ . They are formed: 1. From the osazones either by boiling

with dilute acids (*v. Pechmann, B. 21, 2758*), or by heating (Auwers & V. Meyer, B. 21, 2806) the latter process giving the better yield:

2. From a hydrazone-hydroxim by the action of the chlorides of phosphorus:

(*v. Pechmann, l.c.*).—3. From the osotetrazones (*v. infra*).

The osotriazones are feebly basic, very stable compounds.

**Osotetrazones.** The osotetrazones contain the closed-chain complex  $\begin{array}{c} \text{—C=N—N—} \\ | \quad \diagup \\ \text{—C=N—N—} \end{array}$ . They

are obtained by oxidising the osazones with potassium dichromate in dilute acetic acid solution:

(*v. Pechmann, B. 21, 2755*). They are dark-red neutral compounds, the formation of which has been recommended as a characteristic test for the osazones (*v. P.*).

By boiling the osotetrazones with dilute hydrochloric acid they are converted into osotriazones:

The oxygen is not liberated, but oxidises a portion of the substance (*v. Pechmann, B. 21, 2757*).

Neither the osotriazones nor the osotetrazones have been much studied. F. R. J.  
**HYDRAZOPHENINE**  $\text{C}_{12}\text{H}_9\text{N}_3$ . [174°]. Formed by heating azophenine with alcoholic ammonium sulphide at c. 140°. Colourless needles (O. Fischer & Hepp, B. 20, 2488).

**HYDRAZO-PHENOL** *v. Di-oxo-di-phenyl-hydrazine*.

**HYDRAZO-DIPHENYL**.  $\text{C}_{12}\text{H}_9\text{N}_3$ . *Di-diphenyl hydrazone*. [247°]. Prepared by reducing azoxydiphenyl with alcoholic ammonium sulphide (Zimmermann, B. 13, 1961). White pearly plates, insol. water, sl. sol. alcohol and HOAc, m. sol. ether.

**HYDRAZO-PHENYL-METHYL** *v. s-phenyl-methyl-hydrazine*.

**HYDRAZO-TEREPHTHALIC ACID** *v. Di-phenyl-hydrazine tetra-carboxylic acid*.

**HYDRAZO-TOLUENE** *v. Di-tolyl-hydrazine*.

**HYDRAZO-TOLUIDINE** *v. Di-amido-di-tolyl-hydrazine*.

**HYDRAZO-XYLENE** v. DI-XYL-HYDRAZINE.**HYDRAZULMIN** v. AZULMIC ACID.**HYDRIDES**. Binary compounds of hydrogen.

Hydrogen forms binary compounds with all the distinctly non-metallic elements, also with As and Sb. A hydride of Cu is known, and there probably exists a definite but unstable hydride of Pd, and perhaps of one or two of the other platinum metals. There are also indications of the existence of hydrides of K and Na.

The non-metallic hydrides may be classified in accordance with their composition as follows:—

- (i.) *HM*:  $\text{HF}$ ,  $\text{HCl}$ ,  $\text{HBr}$ ,  $\text{HI}$ .
- (ii.) *H<sub>2</sub>M*:  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{Se}$ ,  $\text{H}_2\text{Te}$ .
- (iii.) *H<sub>3</sub>M*:  $\text{H}_3\text{N}$ ,  $\text{H}_3\text{P}$ ,  $\text{H}_3\text{B}$ ,  $\text{H}_3\text{As}$ ,  $\text{H}_3\text{Sb}$ .
- (iv.) *H<sub>4</sub>M*:  $\text{H}_4\text{C}$ ,  $\text{H}_4\text{Si}$ .
- (v.) *Various*:  $\text{H}_2\text{O}_2$ ,  $\text{H}_2\text{S}_2$ ,  $\text{H}_2\text{P}_2$ ,  $\text{H}_2\text{N}_2$ ; numerous hydrocarbons.

A definite hydride of Cu,  $\text{Cu}_2\text{H}_3$ , has been obtained. It decomposes at  $60^\circ$  into Cu and H. K and Na absorb H rapidly at c.  $300^\circ$ ; compounds,  $\text{K}_2\text{H}$  and  $\text{Na}_2\text{H}$ , appear to be formed. Pd, Pt, Fe, Ni, Au, and some other metals, when used as the negative electrodes in the electrolysis of water, absorb considerable quantities of H. A compound  $\text{Pd}_2\text{H}$  is probably formed. In the other cases it is doubtful whether the absorption is purely physical, or partly chemical and partly physical. As a class, the metals do not form definite hydrides, while the non-metals do form hydrides. The greater number of the non-metallic hydrides may be produced by direct union of their elements; a few are produced by evolving H in contact with solutions of compounds of the elements, e.g.  $\text{AsH}_3$ , and a few by more indirect methods.

The non-metallic hydrides vary much in properties:  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$  are strong acids;  $\text{H}_2\text{S}$  is a very weak acid;  $\text{NH}_3$  is markedly alkaline;  $\text{PH}_3$  is feebly alkaline;  $\text{H}_2\text{O}$  is neutral; hydrocarbons differ extremely in their properties, although none is either distinctly an acid or an alkali. Some hydrides are easily decomposed by heat, e.g.  $\text{H}_2\text{O}_2$ ,  $\text{HI}$ ; others are extremely stable as regards the action of heat, e.g.  $\text{HCl}$ ,  $\text{H}_2\text{O}$ . M. M. P. M.

**HYDRINDIC ACID** is a  $\alpha$ -oxy-o-amido-phenyl-acetic acid, of which di-oxindole is the anhydride.

**HYDRINDINE** v. INDINE.**HYDRINDONAPHTHENE** v. INDONAPHTHENE DIHYDRIDE.**HYDRIODIC ACID** v. IODHYDRIC ACID, vol. iii.

**HYDRO**-. Organic compounds whose names begin with this prefix will usually be found described as hydrides of the substances to whose names it is attached.

Use of this prefix applied to inorganic acids and salts. For hydro-acids and hydro-salts v. the acids or salts sought for. Thus, hydrofluoboric acid will be found under BOROFUORHYDRIC ACID; hydroferrocyanic acid will be found under FERROCYNHYDRIC ACID; hydrofluosilicic acid will be found under SILICATES.

**HYDRO-ACRIDINE** v. ACRIDINE OCTOXYDRIDE.**HYDRO-ANISOIN**

$\text{C}_6\text{H}_4(\text{OMe})\text{CH}(\text{OH})\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{OMe}$ . Di-methoxy-hydro-benzoin.  $[170^\circ\text{--}172^\circ]$ . A small quantity of this body is formed from anisic aldehyde in ethereal solution by sodium amal-

gam (C. Saytzeff, Z. [2] 3, 678; Samosadsky, Z. [2] 4, 644; Rosset, Z. [2] 5, 562; M. Wallach, A. 228, 78). Pyramids, v. sl. sol. warm water, m. sol. ether, v. sol. hot alcohol. When distilled in a current of  $\text{CO}_2$  it partly sublimates, and is partly converted into anisic aldehyde. Conc.  $\text{HNO}_3$  forms nitro-anisic aldehyde. Chromic acid mixture gives anisic acid.  $\text{PCl}_5$  forms  $\text{C}_6\text{H}_4(\text{OMe})_2\text{COCl}$ .

**Ischydroanisoin**  $\text{C}_6\text{H}_4\text{O}_2$ .  $[125^\circ]$ . Separates only after the addition of water to the alcoholic solution of anisic aldehyde, which has been treated with sodium. Slender interlacing needles, v. e. sol. alcohol and ether.

**Deoxyanisoin**  $\text{C}_6\text{H}_4\text{O}_2$ .  $[95^\circ]$ . Formed by boiling hydro-anisoin or iso-hydro-anisoin with dilute  $\text{H}_2\text{SO}_4$ . Tufts of needles, v. sol. alcohol and ether. Oxidised by chromic acid mixture to anisic aldehyde and anisic acid.

**Isomeride of Deoxyanisoin**  $\text{C}_6\text{H}_4\text{O}_2$ .  $[215^\circ]$ . Formed by the action of Zn and  $\text{HCl}$  on hydro-anisoin or on anisic aldehyde. Crystalline; insol. ether.

**HYDRO-ANTHRACENE** v. ANTHRACENE HYDRIDE. A hydride  $\text{C}_{14}\text{H}_{12}$ ,  $[88^\circ]$  (c.  $270^\circ$ ) has been obtained by Lucas (B. 21, 2510) by heating anthracene (3 g.) with red phosphorus (3 g.) and HI (16 g. of S.G. 1.7) for twelve hours at  $250^\circ$ .

**HYDRO-ANTHRACENE CARBOXYLIC ACIDS** v. vol. i. p. 278.**HYDRO-ANTHRANOL** v. ANTHRANOL DIHYDRIDE, vol. i. p. 279.**HYDRO-APOTROPINE** v. ATROPINE.**HYDRO-ATROPIC ACID** v.  $\alpha$ -PHENYL-PROPIONIC ACID.**HYDROBENZAMIDE** v. BENZOIC ALDEHYDE.**HYDRO-BENZENE DI-CARBOXYLIC ACIDS**

v. Hydrides of the PHTHALIC ACIDS.

**HYDROBENZOIC ACID** v. BENZOIC ACID.**HYDROBENZOLIN**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e.

$\text{C}_6\text{H}_4\text{CH}(\text{OH})\text{CH}(\text{OH})\text{C}_6\text{H}_4$ . *Stilbene alcohol*. Mol. w. 214.  $[138^\circ]$  (Paal, B. 16, 637);  $[134^\circ]$  (Zincke);  $[133^\circ]$  (A.). (above  $300^\circ$ ). S.  $25^\circ$  at  $15^\circ$ ; 1.25 at  $100^\circ$ .

**Formation**.—1. By the action of granulated zinc upon benzoic aldehyde dissolved in alcohol which has previously been partially saturated with  $\text{HCl}$ . The hydrobenzoin is ppt. on subsequent addition of water (Zinin, A. 129, 125).—2. Together with ischydrobenzoin and benzyl alcohol by the action of sodium-amalgam on benzoic aldehyde dissolved in alcohol (Ammann Z. [2] 7, 83; A. 168, 69).—3. From benzoin by heating with alcoholic potash at  $155^\circ$  in an exhausted tube, benzoic acid being also formed (Zinin, B. [2] 7, 260).—4. By the action of sodium-amalgam on benzoin (Grimaux, B. 2, 281) or on benzil (Forst a. Zincke, A. 182, 259).—5. From  $\text{C}_6\text{H}_5\text{CHBrCHBrC}_6\text{H}_5$  by treatment with silver acetate or oxalate and saponification of the product (Limpricht a. Schwanert, Z. [2] 8, 684; A. 160, 177).

**Properties**.—Silky needles (from water of dilute alcohol) or monoclinic tables (from absolute alcohol); v. sol. alcohol.

**Reactions**.—1. Nitric acid oxidises it to benzoin and finally to benzil (Zinin).—2. Chromic acid mixture forms benzoic aldehyde (Zincke A. 198, 121).—3.  $\text{PCl}_5$  forms (a) and (b) di-chloro-di-phenyl-ethane  $\text{C}_6\text{H}_4\text{CHClCHClC}_6\text{H}_4$ . 4.  $\text{PBr}_5$  forms in like manner a bromide.

$C_6H_5Br$ .—5. Dilute  $H_2SO_4$  at  $200^\circ$  forms di-phenyl-acetic aldehyde and an anhydride  $C_{12}H_{10}O$  (Breuer a. Zincke, *B.* 11, 72; Weiss, *A.* 248, 84).

*Acetyl derivative*

$C_6H_5CH(OAc).CH(OH).C_6H_5$ . [ $84^\circ$ ]. From hydrobenzoin and  $HOAc$  at  $180^\circ$  (Limpricht a. Schwanert, *A.* 160, 190; Forst a. Zincke, *A.* 182, 254). Long needles (from aqueous  $HOAc$ ), v. e. sol. alcohol, ether, and  $HOAc$ .

*Di-acetyl derivative*  $(C_6H_5)_2C_2H_2(OAc)_2$ : [ $136^\circ$ ]; formed by acetylation of hydrobenzoin, or by the action of zinc-dust on a mixture of benzoic aldehyde and acetyl chloride (Paal, *B.* 16, 686). Formed also from di-bromo-di-phenyl-ethane  $C_6H_5CHBr.CHBr.C_6H_5$  and  $AgOAc$  (Limpricht a. Schwanert, *A.* 160, 177). Monoclinic prisms (from ether); m. sol. cold alcohol, sol. ether and benzene.  $PCl_5$  converts it into (a)-di-chloro-di-phenyl-ethane  $C_6H_5CHCl.CHCl.C_6H_5$ .

*Benzoyl derivative*

$C_6H_5CH(OH).CH(OBz).C_6H_5$ . [ $161^\circ$ ]. Formed, together with the di-benzoyl derivative by heating hydrobenzoin (1 pt.) with  $Bz_2O$  (3 pts.) at  $160^\circ$  (Forst a. Zincke, *A.* 182, 277). Needles or plates (from alcohol); v. sol. alcohol, ether, and chloroform.

*Di-benzoyl derivative*

$Ph.CH(OBz).CH(OBz).Ph$ . [ $246^\circ$ ]. Small white needles, al. sol. most solvents. Formed, together with the di-benzoyl compound of isohydrobenzoin, by the action of zinc-dust on a mixture of benzoic aldehyde and benzoyl chloride (Paal, *B.* 17, 909). Formed also by treating the compound  $PhCHBr.CHBrPh$  with  $AgOBz$  (Forst a. Zincke, *A.* 182, 277).

[ $126^\circ$ ]. Obtained by the action of  $ClCO_2Et$  on the sodium derivative of hydrobenzoin, which is itself got by heating hydrobenzoin in benzene solution with sodium-amalgam (Wallach, *A.* 226, 81). Needles (from alcohol). Saponified by alcoholic  $KOH$ .

[ $132^\circ$ ]. Formed by boiling hydrobenzoin with dilute (20 p.c.) sulphuric acid, distilling off di-phenyl-acetic aldehyde and extracting the residue with ether. Monoclinic crystals (from ether). Not volatile with steam. Insol. water, v. sol. benzene,  $HOAc$ , and hot alcohol. At  $150^\circ$  it splits up into *s*-di-phenyl-ethylene and benzoic aldehyde. *Reactions*.—1. When heated for 17 hours with  $Bz_2O$  at  $240^\circ$  it gives di-benzoyl hydrobenzoin and some *s*-di-phenyl-ethylene.—2.  $HOAc$  at  $170^\circ$  forms di-acetyl-hydrobenzoin.—3.  $Ac_2O$  does not act below  $240^\circ$ , at which temperature it gives di-acetyl-hydrobenzoin, *s*-di-phenyl-ethylene, and benzoic aldehyde.—4.  $BzCl$  gives (a)-di-chloro-di-phenyl-ethane  $Ph.CHCl.CHCl.Ph$  [ $192^\circ$ ].  $PCl_5$  forms the same body.—5. By heating for 8 hours at  $200^\circ$  with conc.  $HIAq$  and phosphorus it is reduced to *s*-di-phenyl-ethane [ $52^\circ$ ].—6.  $CrO_3$  in  $HOAc$  forms  $C_{12}H_{10}O_2$ , which crystallises from hot alcohol in small felted needles [ $155^\circ$ ] and  $C_{12}H_{10}O_3$  [ $145^\circ$ ] (Breuer a. Zincke, *A.* 198, 169).—7. Dilute (20 p.c.)  $H_2SO_4$  at  $200^\circ$  forms di-phenyl-acetic aldehyde.—

8.  $HClAq$  (S.G. 1.19) at  $170^\circ$  gives di-phenyl-acetic aldehyde and (a)-di-chloro-di-phenyl-ethane.

*Isohydrobenzoin*  $C_6H_5O$ , i.e.

$C_6H_5CH(OH).CH(OH).C_6H_5$ . [ $120^\circ$ ]. S. 19 at  $15^\circ$ ; 1.25 at  $100^\circ$ . Formed, together with a smaller quantity of hydrobenzoin, when sodium-amalgam acts on benzoic aldehyde in presence of water. The presence of alcohol diminishes the proportion of isohydrobenzoin to hydrobenzoin (Ammann a. Fittig, *A.* 168, 70). The separation may be effected by repeated crystallisation from alcohol, in which isohydrobenzoin is somewhat the more soluble. Formed also by saponifying its di-acetyl derivative. Glistening hydrated needles (from water), anhydrous hexagonal crystals (from alcohol), or monoclinic prisms (from ether). The hydrated crystals melt at  $96^\circ$ . V. sol. alcohol, ether, and chloroform.

*Reactions*.—1.  $PCl_5$  gives (a)-di-chloro-di-phenyl-ethane  $Ph.CHCl.CHCl.Ph$  [ $184^\circ$ ], and a resinous compound  $C_{12}H_{10}ClO$  [ $150^\circ$ ] (Breuer a. Zincke, *A.* 198, 167).—2. Boiling dilute  $H_2SO_4$  forms di-phenyl-acetic aldehyde and the anhydride  $C_{12}H_{10}O$  [ $102^\circ$ ].—3. By heating with  $Bz_2O$  there is formed mono- and di-benzoyl-isohydrobenzoin and also di-benzoyl hydrobenzoin.

*Sodium derivative*

$Ph.CH(ONa).CH(ONa).Ph$  (?). In an ethereal solution of isohydrobenzoin sodium-amalgam forms a powdery sodium derivative. Some of the isohydrobenzoin appears to be changed at the same time into a crystalline isomeride [ $125^\circ$ ], which is slowly dissolved by boiling water, being changed to isohydrobenzoin.

*Acetyl derivative*

$C_6H_5CH(OH).CH(OAc).C_6H_5$ . [ $88^\circ$ ]. Formed by the action of  $KOAc$  or of  $AgOAc$  on  $Ph.CHBr.CHBr.Ph$  (Forst a. Zincke, *A.* 182, 282). Short thick needles.

*Di-acetyl derivative*

$C_6H_5CH(OAc).CH(OAc).C_6H_5$ . [ $118^\circ$ ]. Formed by digesting isohydrobenzoin with acetyl chloride for 24 hours. Formed also by boiling  $Ph.CHBr.CHBr.Ph$  (1 pt.) dissolved in  $HOAc$  (3 pts.) with an excess of  $KOAc$  for 12 hours (Zincke, *A.* 182, 262; 198, 154). Plates (from alcohol). Occurs sometimes in trimetric prisms [ $106^\circ$ ]. V. sol. alcohol, ether, and chloroform.

*Benzoyl derivative*

$C_6H_5CH(OH).CH(OBz).C_6H_5$ . [ $130^\circ$ ]. Formed together with the di-benzoyl derivative, by heating isohydrobenzoin with excess of  $Bz_2O$  at  $160^\circ$  (Forst a. Zincke, *A.* 182, 285). Small needles (from dilute alcohol). V. e. sol. alcohol, ether and chloroform.

*Di-benzoyl derivative*  $C_{12}H_{10}(OBz)_2$ , [ $151^\circ$ ]; fine silky needles; v. e. sol. ordinary solvents. Formed, together with the di-benzoyl derivative of hydrobenzoin, by the action of zinc-dust on a mixture of benzoic aldehyde and benzoyl chloride (Paal, *B.* 17, 909). Formed also, together with its isomeride, by heating isohydrobenzoin with  $Bz_2O$ ; also by the action of  $Ph.CHBr.CHBr.Ph$  on  $AgOBz$ .

*Carbonyl derivative*  $\begin{array}{c} \text{Ph.CH.O} \\ \diagdown \quad \diagup \\ \text{Ph.CH.O} \end{array} \text{CO.}$  [ $110^\circ$ ]. Prepared by dissolving benzoic aldehyde and  $Cl.CO_2Et$  in ether and treating with sodium amalgam. A violent reaction occurs;

when it abates the flask is heated for some time with inverted condenser. The liquid is filtered and evaporated, the residue is crystallised from alcohol. The yield is bad. Formed also by treating the sodium derivative of isohydrobenzoin in ether or benzene with  $\text{ClCO}_2\text{Et}$ , an intermediate body  $\text{Ph}.\text{CH}(\text{OCO}_2\text{Et}).\text{CH}(\text{OCO}_2\text{Et}).\text{Ph}$  being perhaps formed. Monoclinic plates (from alcohol). Insol. cold water, sl. sol. boiling water. Sl. sol. cold alcohol or ether. Insol.  $\text{CS}_2$ , sol. benzene. Decomposed by boiling potash into potassium carbonate and iso-hydro-benzoin. It is not affected by  $\text{Ac}_2\text{O}$ .  $\text{PCl}_5$  converts it into (a)-di-chloro-s-di-phenyl-ethane [186°] (Wallach, *J. pr.* [2] 25, 262; A. 226, 80).

**Anhydride**  $\text{C}_{16}\text{H}_{14}\text{O}_4$  [102°]. Formed, like the corresponding anhydride of hydrobenzoin, by boiling isohydrobenzoin with dilute  $\text{H}_2\text{SO}_4$  (Zincke & Breuer). Monoclinic crystals (from ether). More soluble in alcohol than its isomeride.

**Reactions.**—1. When heated with  $\text{Bz}_2\text{O}$  it gives s-di-phenyl-ethylene and di-benzoyl-isohydrobenzoin. —2.  $\text{HOAc}$  has no action even at 250°. —3.  $\text{Ac}_2\text{O}$  does not act at 170°. —4.  $\text{BzCl}$  yields  $\text{Ph}.\text{CHCl}.\text{CHCl}.\text{Ph}$  [192°].  $\text{PCl}_5$  forms a compound  $\text{C}_{16}\text{H}_{14}\text{Cl}_2\text{O}$ , which is finally converted into  $\text{Ph}.\text{CHCl}.\text{CHCl}.\text{Ph}$ . —5.  $\text{HI}$  and  $\text{P}$  at 200° form s-di-phenyl-ethane [52°]. —6.  $\text{CrO}_3$  in  $\text{HOAc}$  acts upon it in the same way as upon its isomeride.

**HYDROBENZON-DI-*p*-CARBOXYLIC ACID**  $\text{C}_{16}\text{H}_{12}\text{O}_6$ , i.e.  $\text{C}_6\text{H}_4(\text{CO}_2\text{H}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{C}_6\text{H}_4(\text{CO}_2\text{H})$ . Obtained by reduction of the sodium salt of benzoin-di-carboxylic acid with sodium-amalgam. Infusible. Unsublimable (Oppenheimer, *B. 19*, 1817).

**HYDROBERBERINE** v. BERBERINE.

**HYDROBROMIC ACID** v. BROMHYDRIC ACID, vol. i. p. 532.

**HYDRO-BROMO-CINCHENE** v. CINCHENE BROMOHYDRIDE.

**HYDRO-BROMO-CINCHONINE** v. CINCHONINE BROMOHYDRIDE.

**HYDROBUTYRAMIDE** v. ISOBUTYRIC ALDEHYDE.

**HYDROBUTYROFURONIC ACID**  $\text{C}_8\text{H}_{10}\text{O}_5$ , i.e.  $\text{CO}_2\text{H}.\text{CH}_2.\text{CH}_2.\text{CO}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CO}_2\text{H}$ . An indistinctly crystalline acid formed by reducing butyro-furonic acid  $\text{C}_8\text{H}_{10}\text{O}_5$  with sodium-amalgam (Tönnies, *B. 12*, 1201).— $\text{Ag}_2\text{A}''$ .

**HYDRO-CAFFURIC ACID** v. CAFFEINE.

**HYDROCAMPHENE** v. DECINENE.

**HYDROCARBONS.** Compounds containing carbon and hydrogen only. Liquid hydrocarbons, especially terpenes  $\text{C}_{10}\text{H}_{16}$ , and their isomerides, are commonly found in essential oils from plants; solid hydrocarbons have been obtained from the fruit of *Heracleum Sphondylium*, *H. giganteum*, *Pastinaca sativa*, and from other plants (Guthzeit, *B. 21*, 2881). The chief source of hydrocarbons is, however, the dry distillation of organic bodies, the nature of the product depending upon the temperature at which the distillation takes place, since a red heat tends to deprive hydrocarbons of a part of their hydrogen. Thus when coal is distilled at the lowest possible temperature, the distillate consists chiefly of paraffins and olefines; while distillation at a bright-red heat forms large quantities

of aromatic hydrocarbons. American petroleum, formed by the slow decomposition of vegetable matter under the surface of the earth, probably at a moderate temperature, is very largely composed of paraffins (*cf.* Engler, *B. 21*, 1816).

The hydrocarbons are insoluble in water; they are neutral, and do not form salts with acids or alkalis; they are not saponified by boiling with dilute acids or alkalis, and are for the most part not affected by that treatment. They do not unite with alkaline bisulphites, nor do they react with hydroxylamine or phenyl hydrazine.

According to Berthelot (*C. R.* 84, 714) when liquid hydrocarbons are decomposed by passing powerful induction sparks through them the gases given off consist of hydrogen, methane, ethane, ethylene, and acetylene, but no hydrocarbon of higher molecular weight; carbon is deposited in the case of terpenes and aromatic hydrocarbons, but not from paraffins.

The hydrocarbons with which bromine combines even in the dark are known as unsaturated fatty hydrocarbons; the remaining hydrocarbons may be divided into saturated fatty hydrocarbons and aromatic hydrocarbons, which may be distinguished by treatment with fuming nitric acid, which forms nitro-derivatives with aromatic hydrocarbons, but never does so with the saturated fatty hydrocarbons.

The saturated fatty hydrocarbons are also called paraffins, and contain a larger percentage of hydrogen than any other hydrocarbons; they may be included in the general formula  $\text{C}_n\text{H}_{2n+2}$ . Unsaturated fatty hydrocarbons of the formula  $\text{C}_n\text{H}_{2n}$  are called olefines, since olefant gas is the first member of the series. Of the hydrocarbons  $\text{C}_n\text{H}_{2n-2}$  those which give pps. with ammoniacal solutions of cuprous chloride and of silver nitrate are held to contain the group  $\text{C}\equiv\text{CH}$  and belong to the acetylene series.

Vowel nomenclature, first proposed by Laurent in naming the chlorinated derivatives of naphthalene, was adopted by Hofmann to distinguish the different classes of hydrocarbons. Thus, according to Hofmann, the names of the compounds:

$\text{C}_n\text{H}_{2n+2}$  end in —ane  
 $\text{C}_n\text{H}_{2n}$  " —ene  
 $\text{C}_n\text{H}_{2n-2}$  " —ine  
 $\text{C}_n\text{H}_{2n-4}$  " —one  
 $\text{C}_n\text{H}_{2n-6}$  " —tune.

Inasmuch as *ene* is the usual termination of bases, and *one* that of ketones, in this dictionary the names of unsaturated hydrocarbons have been made to end in *ene*, thus:

Hydrocarbons  $\text{C}_n\text{H}_{2n}$  end in —ylene  
 "  $\text{C}_n\text{H}_{2n-2}$  " —inene  
 "  $\text{C}_n\text{H}_{2n-4}$  " —onefine  
 "  $\text{C}_n\text{H}_{2n-6}$  " —unene.

**Paraffins.** The saturated fatty hydrocarbons or paraffins are named as follows:

Methane  $\text{CH}_4$   
 Ethane  $\text{C}_2\text{H}_6$   
 Propane  $\text{C}_3\text{H}_8$   
 Butane  $\text{C}_4\text{H}_{10}$   
 Pentane  $\text{C}_5\text{H}_{12}$   
 Hexane  $\text{C}_6\text{H}_{14}$   
 Heptane  $\text{C}_7\text{H}_{16}$   
 Octane  $\text{C}_8\text{H}_{18}$

Ennane or Nonane	$C_9H_{20}$
Decane	$C_{10}H_{22}$
Undecane or Undecane	$C_{11}H_{24}$
Dodecane	$C_{12}H_{26}$
Tridecane	$C_{13}H_{28}$
Tetradecane	$C_{14}H_{30}$
Pentadecane	$C_{15}H_{32}$
Hexadecane	$C_{16}H_{34}$
Heptadecane	$C_{17}H_{36}$
Octadecane	$C_{18}H_{38}$
Enndecane	$C_{19}H_{40}$
Icosane	$C_{20}H_{42}$
Hentiicosane	$C_{21}H_{44}$
Do-icosane	$C_{22}H_{46}$
Tri-icosane	$C_{23}H_{48}$
Triacotane	$C_{24}H_{50}$

From a structural point of view any paraffin may be regarded as formed from the next lower homologue by displacement of H by  $CH_2$ . As the hydrogen atoms in methane are similarly situated there can be only one ethane, and as the atoms of hydrogen in ethane  $CH_3CH_3$  are similarly situated there can be only one propane. But in propane  $CH_3CH_2CH_3$  it is possible to displace a hydrogen atom either in the methylene group  $CH_2$  or in one of the two methyl groups; thus we arrive at two butanes:  $CH_3CH(CH_3)CH_3$  and  $CH_3CH_2CH_2CH_3$ .

Proceeding in this way we find that there are theoretically possible 3 pentanes, 5 hexanes, 9 heptanes, 18 octanes, 35 ennanes, 75 decanes, 159 hendecanes, 355 dodecanes, 802 tridecanes, &c.

The paraffins are said to be normal when they contain only two methyl groups, and may consequently be represented by a chain that has no branches, e.g.  $CH_3CH_2CH_2CH_2CH_2CH_3$ . The boiling-points of the normal paraffins are:

Pentane	(37°)
Hexane	(70°)
Heptane	(99°)
Octane	(124°)

after which they rise 19° for each increment of  $CH_2$ . The other paraffins boil at lower temperatures than their normal isomerides.

**Occurrence.**—Among the products of the destructive distillation of coal, bituminous shale, peat, &c.; and in American petroleum. Natural or artificial petroleum yields on distillation: (a) petroleum ether or ligroin boiling from 35° to 90°, containing chiefly pentane, hexane, and heptane; (b) benzoline or petroleum spirit, boiling from 90° to 150° and containing heptane, octane, and ennane; (c) kerosene, petroleum-naphtha, or paraffin oil boiling from 150° to 300°, containing decane, hendecane, and dodecane; (d) solid paraffin wax, a mixture of saturated hydrocarbons of still higher molecular weight (Greville Williams, *Tr.* 1857, 737; *C. J.* 15, 130; Schorlemmer, *C. J.* 15, 419; Pelouze & Cahours, *A.* 124, 289; 127, 196; 129, 87).

**Formation.**—1. By distilling the acids  $C_nH_{2n+2}O_2$  with excess of potash, lime, or baryta. 2. By the action of water on the zinc alkyls; this reaction may be carried out by simply heating the alcoholic iodide with zinc and water, or by treating them with fine copper-zinc couple in presence of water or alcohol.—3. By the reduction of the chlorides or iodides of alcohol radicals by zinc and hydrochloric acid, by  $H_2$ , or by

sodium-amalgam.—4. By the action of sodium or of reduced silver on an iodide or mixture of iodides  $RI + RI + Na_2 = 2NaI + RR'$ . This process is known as Wurtz's reaction (Wurtz, *A. Ch.* [3] 44, 275).—5. By the action of alcoholic iodides on zinc-alkyls.—6. By the electrolysis of the sodium salts of the fatty acids.

**Properties.**—Methane, ethane, propane, and butane are gaseous at ordinary temperatures; the specific gravity of the higher paraffins in the liquid state steadily rises with increasing molecular weight. The paraffins are distinguished by their chemical indifference (*parum affinis*). They are not attacked by KOH, by  $H_2SO_4$ , or by cold fuming  $HNO_3$ .

**Reactions.**—1. Chlorine acting on a normal paraffin forms only primary, and secondary chlorides, the latter containing the group  $CHClCH_2$ . Bromine forms, however, only secondary bromides of similar constitution (Schorlemmer). The isomeric mono-chlorinated paraffins got from petroleum yield, by abstracting HCl, a mixture of olefines one portion of which combines readily with cold HCl, whilst the rest only combines on heating. The chloro-derivatives formed in the cold distil with partial decomposition and at a lower temperature than those formed by heating. The latter distil without decomposition and have the general formula  $CH_3CHClC_nH_{2n+1}$  (Schorlemmer, *C. J.* 26, 319; *Pr.* 29, 864; *T.* 171, 451; Morgan, *C. J.* 28, 801; Le Bel, *Bl.* [2] 28, 460).—2. Bromine does not act upon them in the dark, in sunlight its colour disappears, a molecule of HBr being formed for each molecule of bromine used up.—3. Hypochlorous acid does not unite with paraffins.—4. Chromic acid and hot nitric acid (S.G. 1.4 to 1.5) oxidise them to  $CO_2$ , forming in some cases intermediate fatty acids (Schorlemmer, *Pr.* 16, 373).

**Olefines**  $C_nH_{2n}$ . The names of the olefines are:—

Ethylene	$C_2H_4$
Propylene	$C_3H_6$
Butylene	$C_4H_8$
Amylene	$C_5H_{10}$
Hexylene	$C_6H_{12}$

The higher members are named by writing -ylene in place of the -ane in the names of the paraffins (*v. supra*). Methylene  $CH_2$  does not appear capable of existing; in reactions where it might be expected ethylene is formed instead. It will be observed that the olefines have all the same percentage composition. The hydrocarbons in Caucasian petroleum, although isomeric with the olefines, appear to be hexahydrides of the homologues of benzene (Markownikoff, *B.* 20, 1850).

**Formation.**—1. By dehydration of the saturated fatty-monohydric alcohols  $C_nH_{2n+2}O$ . This may be done by means of  $H_2SO_4$ ,  $ZnCl_2$ , or  $P_2O_5$ . In the case of the higher alcohols a mixture of hydrocarbons is, however, produced. 2. By the action of alcoholic KOH on the alkyl iodides.—3. By passing alkyl chlorides over red-hot lime. In some cases mere distillation is sufficient to split up the alkyl chlorides into olefine and HCl.—4. A large number of olefines are produced in the manufacture of illuminating gas from oil (Armstrong, *C. J.* 40, 74).—5. By

the electrolysis of the alkaline salts of dibasic fatty acids.

**Reactions.**—1. The olefines combine readily with chlorine, bromine, and iodine forming oily compounds (e.g. Dutch liquid); hence their name.—2. They combine with  $\text{SO}_2$ , and are therefore absorbed by Nordhausen sulphuric acid. Conc.  $\text{H}_2\text{SO}_4$  forms alkyl sulphuric acids.—3. They combine with  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$ . Conc.  $\text{HIAg}$ , however, at  $100^\circ$ , soon reduces them to paraffins. Olefines of the formula  $\text{CH}_2\text{:CHR}$  combine with  $\text{HCl}$  only on heating (Le Bel, *B.* [2] 28, 460). Those of the formulae  $\text{CH}_2\text{:CR}'\text{R}'$  or  $\text{CHR:CHR}'$  combine with cold  $\text{HCl}$  (Le Bel; cf. Schorlemmer a. Thorpe, *A.* 217, 151).—4. Alkaline  $\text{KMnO}_4$  oxidises them to oxalic, acetic, formic, carbonic, and other acids (Berthelot, *C. R.* 64, 35).—5. Many olefines may be oxidised by  $\text{CrO}_3$  to aldehydes or ketones (Berthelot, *C. R.* 68, 334).—6.  $\text{HClO}$  unites forming chlorhydrins of dihydric alcohols or glycols. A very simple method of preparing hypochlorous acid for employment in the preparation of organic chlorhydrins consists in acidifying a solution of bleaching powder with boric acid. The theoretical quantity of the unsaturated organic compound is then added, allowed to stand for some time in the dark, and the chlorhydrin extracted with ether (Lauch, *B.* 18, 2287).—7. The olefines are prone to polymerisation especially in presence of  $\text{ZnCl}_2$  or  $\text{H}_2\text{SO}_4$ .

**Acetylene series  $\text{C}_2\text{H}_{2n-2}$ .** The hydrocarbons  $\text{C}_2\text{H}_{2n-2}$  may be divided into (a) acetylenes proper:  $\text{R}_2\text{C}\equiv\text{CH}$ ; (b) dialkyl acetylenes:  $\text{RCH}\equiv\text{CR}'$ ; (c) di-ethylenic hydrocarbons:  $\text{RCH}=\text{CH}\cdot\text{CH}=\text{CHR}'$ ; and (d) isoallylenes:  $\text{RR}'\text{C}::\text{CR}''\text{R}'''$  (cf. Béhal, *A. Ch.* [6] 15, 268).

**Formation.**—1. By heating bromo-olefines, or the dibromides of olefines with alcoholic potash. Thus they may readily be obtained from aldehydes and ketones by successive treatment with  $\text{PCl}_5$  and alcoholic potash.—2. By electrolysis of the sodium salt of unsaturated dibasic acids.—3. In the destructive distillation of organic bodies, and in the incomplete combustion of coal-gas.

**Reactions.**—1. The hydrocarbons  $\text{RC}\equiv\text{CH}$  form sps. in ammoniacal solutions of cuprous chloride and of silver nitrate. These sps. are decomposed by  $\text{HCl}$  with liberation of the hydrocarbon.—2. They combine with either one or two molecules of bromine,  $\text{HCl}$ ,  $\text{HBr}$ ,  $\text{HI}$ , and  $\text{HOCl}$ .—3. By successive treatment with  $\text{H}_2\text{SO}_4$  and water they can be hydrated; acetylene changing to aldehyde, and allylene to acetone.—4. The hydrocarbons  $\text{RC}\equiv\text{CH}$  give sps. in an aqueous solution of  $\text{HgCl}_2$ ; when the product is treated with acids aldehydic or ketonic products of hydration are liberated (Kwatscheroff, *B.* 17, 13).—5. A saturated alcoholic solution of  $\text{AgNO}_3$  gives crystalline sps. with acetylenic hydrocarbons; thus heptene gives  $\text{C}_7\text{H}_{12}$ ,  $\text{AgAgNO}_3$ , which deflagrates when heated (Béhal, *A. Ch.* [6] 15, 428).—6.  $\text{KMnO}_4$  and chromic acid attack the hydrocarbons at the unsaturated point; thus diallyl gives  $\text{CO}_2$  and succinic acid. Béhal (*A. Ch.* [6] 16, 368) thinks that no hydrocarbon of the isoallylene type has as yet been isolated. Thus by heating  $\text{CH}_3\text{Cl}\cdot\text{CH}::\text{CHCl}$  in dry benzene with sodium he failed to obtain isoallylene. He was equally unable to obtain  $\text{CH}_3\text{C}::\text{CH}$ , by heat-

ing  $\text{CH}_3\text{Cl}\cdot\text{CHCl}\cdot\text{CH}_3$  with sodium; while allyl iodide heated with  $\text{PbO}$  in excess only gave propylene; and by heating with  $\text{HgO}$ ,  $\text{CuO}$ , or  $\text{Ag}_2\text{O}$  at  $125^\circ$ – $150^\circ$ ,  $\text{CO}$  is formed, but no isoallylene. When allyl alcohol is dehydrated by  $\text{P}_2\text{O}_5$ , no trace of isoallylene is obtained, the products being ethylene and propylene. Ethyl allyl oxide behaves in like manner, the decomposition proceeding with greater regularity (Béhal, *A. Ch.* [6] 16, 360). According to Gustafson (*J. pr.* [2] 33, 203), however, isoallylene can be obtained by the action of zinc-dust on di-bromo-propylene  $\text{CH}_2\text{Br}\cdot\text{CBr}\cdot\text{CH}_2$  in presence of alcohol. He describes it as a gas which unites with bromine forming  $\text{C}_3\text{H}_5\text{Br}_2$ , and which, when treated with  $\text{H}_2\text{SO}_4$ , and water successively, yields acetone.

**Benzene series  $\text{C}_6\text{H}_{2n-6}$ .** The hydrocarbons of this series are named as follows:—

Benzene  $\text{C}_6\text{H}_6$ ,  
Toluene  $\text{C}_6\text{H}_8$  or  $\text{C}_6\text{H}_7\cdot\text{CH}_3$ ,  
Xylene  $\text{C}_6\text{H}_{10}$  or  $\text{C}_6\text{H}_4(\text{CH}_3)_2$ ,  
Mesitylene and  $\psi$ -cumene  $\text{C}_6\text{H}_{12}$  or  $\text{C}_6\text{H}_2(\text{CH}_3)_3$ ,  
Durene  $\text{C}_6\text{H}_{14}$  or  $\text{C}_6\text{H}_4(\text{CH}_3)_4$ .

Propyl-benzene is called cumene, and propyl-toluene is called cymene, the other members being usually named as substitution derivatives of benzene. Their constitution is discussed under BENZENE (*q. v.*).

**Occurrence.**—In coal-tar, in Galician petroleum, and as hydrides in Caucasian petroleum.

**Formation.**—1. By distilling their carboxylic acids with lime.—2. By adding strips of sodium to an ethereal solution of a mixture of an aromatic bromide and an alkyl iodide (or bromide) (Fittig's reaction). This reaction takes place the more readily the higher the molecular weight of the alkyl iodide, and where there is already a side chain it succeeds best when this is in the para-position (Kraft a. Göttig, *B.* 21, 3184).—3. By adding  $\text{AlCl}_3$  to a mixture of an aromatic hydrocarbon with an alkyl chloride,  $\text{HCl}$  being evolved (Friedel a. Crafts, *A. Ch.* [6] 1, 459; 14, 457; cf. ALUMINIUM CHLORIDE, vol. i. p. 147). Friedel a. Crafts consider that this reaction takes place in two stages:

the latter reaction being analogous to

They have, however, hitherto failed to isolate the hypothetical intermediate body  $\text{C}_6\text{H}_5\text{AlCl}_2$ , but they have equally failed to obtain the compounds  $\text{AlCl}_3(\text{C}_6\text{H}_5)$ , and  $\text{AlBr}_3(\text{C}_6\text{H}_5)$ , described by Gustafson (*J. R.* 1882, 854), which they regard as mixtures. When  $\text{MeCl}$  acts on benzene (5 pts.) containing  $\text{AlCl}_3$  (1 pt.) there is formed *s*-durene.  $\text{MeCl}$  acting on toluene in presence of  $\text{AlCl}_3$  forms *o*-, *m*-, and *p*-xylene,  $\psi$ -cumene, mesitylenes, and *u*-durene, penta-methyl-benzene, and hexa-methyl-benzene (Ador a. Rilliet *B.* 12, 329; O. Jacobsen, *B.* 14, 2627).  $\text{MeCl}$  and  $\text{AlCl}_3$  converts the three xylenes into  $\psi$ -cumene, *m*-xylene giving also mesitylene. The higher homologues of benzene are more readily methylated than the lower. Ethylene passed through a heated mixture of benzene and  $\text{AlCl}_3$  give ethyl-, di-ethyl-, and tri-ethyl-benzene (Balsch *B.* [2] 31, 539). Isomeric changes often occur in these syntheses. Thus isobutyl bromide (800 g.) acting on benzene (900 g.) and  $\text{AlCl}_3$  (800 g.) at  $0^\circ$  forms *tert*-butyl-benzene (167 g.)

736 mm.), which is also got from *tert*-butyl chloride; while *n*-butyl chloride gives *sec*-butylbenzene (174° at 736 mm.) (Schramm, *M.* 9, 513). In like manner isoamyl chloride gives an amylbenzene (188° at 737 mm.) which appears to be  $C_6H_5.CHMMePr$  or  $C_6H_5.CMe_2Et$ . *n*-Propyl bromide gives isopropyl derivatives, since  $PrBr$  is changed to  $PrBr$  in presence of  $AlCl_3$  (Kekulé & Schrötter, *B.* 12, 2280). Schramm supposes the alkyl chloride to be split up into  $HCl$  and olefine, the latter then acting like ethylene (*v. supra*). By the action of  $AlCl_3$  on boiling toluene there is formed benzene, ethylbenzene, and the three xylenes (Friedel & Crafts, *C. R.* 101, 1218). In a similar manner *m*-xylene is converted by  $AlCl_3$  into benzene, toluene, mesitylene, and *p*-cumene; while ethylbenzene gives benzene and diethylbenzene (Anschütz & Immendorff, *B.* 17, 2816; 18, 667). The transference of side chains may be readily effected by passing  $HCl$  through the heated mixture of  $AlCl_3$  with the hydrocarbon, *e.g.*

(Jacobsen, *B.* 18, 343).—4. When aromatic hydrocarbons are heated with  $MeI$  or  $EtI$  and iodine in sealed tubes at high temperature,  $Me$  or  $Et$  can be introduced, although very many other products are formed at the same time. In this way benzene heated with  $MeI$  gives toluene, toluene (with  $MeI$ ) gives xylenes, and hydrocarbons  $C_6H_5$ ,  $C_6H_4$ , and  $C_6H_3$ ; while pseudocumene mixed with mesitylene (with  $EtI$ ) gives  $C_6H_5Me$ ,  $Et$  (here  $Et$  turns out  $Me$ ) (Rayman & Preis, *A.* 223, 315).—5. By heating ketones with  $H_2SO_4$ ; thus acetone gives mesitylene.—6. By heating benzene and its homologues with  $ZnCl_2$  and (the higher) fatty alcohols, water being eliminated (Goldschmidt, *B.* 15, 1066).—7. By heating diazo compounds with alcohol.—8. By oiling hydrazines with  $CuSO_4$  or  $FeCl_3$ .

**Reactions.**—1. Fuming nitric acid dissolves them, and on adding water nitro-derivatives are produced.—2. Fuming sulphuric acid dissolves them, forming sulphonic acids. By distilling the resulting sulphonic acids with superheated steam the hydrocarbons can be recovered, and thus separated from fatty hydrocarbons, and even from one another (Beilstein, *Ar.* 183, 34; Armstrong & Miller, *C. J.* 46, 148; Kelbe, *B.* 19, 93).—3. **Halogens** form products by substitution. Heat and direct sunshine both cause the halogen to enter the side chain instead of the benzene nucleus (Schramm, *B.* 19, 212; *M.* 8, 299). Yellow light has the maximum effects. According to Radziszewski (*A.* 218, 396) the halogens acting upon alkyl-benzenes go in the cold into the *g*-position; as the heat is raised they go into the *o*-position, then into the  $CH_2$  attached to the  $C_6H_5$ , and at a still higher temperature into the next  $CH_2$ , and so on (*v.* CHLORO-COMPOUNDS, and BROMO-COMPOUNDS).—4. **Chromic acid** mixture oxidises all the side chains to carboxyl, while nitric acid ( $S.G. 1.2$ ) frequently attacks only one side chain. In the oxidation by means of dilute  $HNO_3$  of the di-alkylated benzenes it has usually been assumed that the longest side chain is oxidised first, becoming  $CO_2H$ . This is not always the case, for *m*- and *p*-iso-butyltoluenes give isobutylbenzoic acids, and the

oxidation of all such hydrocarbons is greatly modified by the introduction of halogens into the ring, thus tetra-chloro-*m*-isocymene can only be oxidised with very great difficulty, and then is entirely broken up (Kelbe & Pfeiffer, *B.* 19, 1723). Propyl-isopropylbenzene is oxidised to *n*-propylbenzoic acid.—5. **Chromyl chloride** forms addition compounds  $C_6H_5(CrO_2Cl)_2$ . These compounds give off  $HCl$  at 200°, becoming  $C_6H_5(CrO_2Cl)$ . If they contain methyl they are converted by water into aldehydes. In the case of benzene, water produces quinone (Étard, *A. Ch.* [5] 22, 218; *C. R.* 87, 989).—6. By heating with  $HIAg$  the hydrocarbons  $C_6H_5$  can be made to take up 2, 4, or 6 atoms of hydrogen. The hydrides  $C_6H_5H_2$  occur in Caucasian petroleum (Beilstein & Kurbatoff, *B.* 13, 1818) and may also be obtained by the distillation of colophony (Renard, *A. Ch.* [6] 1, 227).

Homologues of Anthracene  $C_{14}H_{10}$  may be formed as follows: 1. From anthracene by abstraction of water (Liebermann & Tobias, *B.* 14, 795).—2. From halogenated hydrocarbons, by heating under pressure (Dorp, 4, 169, 210).—3. From halogenated methanes, aromatic hydrocarbons, and  $AlCl_3$  (Anschütz & Romig, *B.* 18, 664; Elbs & Wittich, *B.* 18, 348).—4. From homologues of diphenylmethane by abstraction of hydrogen (Weiler, *B.* 7, 1185; Fischer, *B.* 7, 1195).—5. From homologues of *o*-tolyl-phenyl ketone by abstraction of water (Behr & Dorp, *B.* 7, 17; Elbs, *J. pr.* [2] 33, 186).—6. Phthalic anhydride, aromatic hydrocarbons, and  $AlCl_3$  give homologues of *o*-benzoylbenzoic acid, whence by conc.  $H_2SO_4$  homologues of anthraquinone may be obtained. Thus tolylbenzoic acid [ $2:1C_6H_4(CO_2H)CO_2C_6H_4(CH_3)$ ] (1:4) from phthalic anhydride and toluene gives (*B.* 2)-methylanthraquinone [175°], while *m*-xylyl-*o*-benzoic acid gives a dimethylanthraquinone [162°] (Elbs, *J. pr.* [2] 33, 318).

**Hydrocarbons of the tri-phenyl-methan series**  $C_{18}H_{14}$  (Elbs, *J. pr.* [2] 33, 181) may be formed as follows: 1. From chloroform or chloro-picrin, benzene or homologues of benzene, and  $AlCl_3$ .—2. From benzylidene chloride, benzene or homologues of benzene, and zinc dust.—3. From secondary aromatic alcohols, aromatic hydrocarbons, and  $P_2O_5$  (best method).—4. From aromatic (*B*)-pinacolins and alkalis (Thörner & Zincke, *B.* 10, 1475; 11, 65).—5. From benzylidene chloride (or its homologues) and  $Hg(C_2H_5)_2$  (or its homologues).—6. From benzoic aldehyde, benzene or its homologues, and  $ZnCl_2$  at 250°.

**HYDROCINNAMIC ACID** *γ.* PHENYL-PROPIONIC ACID.

**HYDROCINNAMIDE**  $C_9H_9N$ , *is.*  $N_2(CH_2CH:CHPh)_2$ . [106°]. White needles. Formed by the action of  $NH_3$  on an alcoholic or ethereal solution of cinnamic aldehyde. It is very stable towards HCl at a high temperature.

**Salts.**— $BHCl8aq$ : flat colourless tables: [220°]; sol. alcohol and chloroform, insol. water, ether, benzene, and ligroin. —  $B_2H_2Cl_4PtCl_4$  (Laurent, *Rev. Scient.* 10, 119; *Peigne*, *B.* 17, 2110).

**HYDROCOLLIDINE** *v.* TRI-METHYL-PYRIDINE HYDRIDE.

**HYDROCONQUININE** *v.* CINCHONA BASES.

**HYDROCORNICULARIC ACID** *v.* CORNICULARIC ACID.

**HYDROCOTARNINE** *v.* NARCOTINE.

**HYDROCOTOIN** *v.* COTO BARK.

**HYDROCOTONE** *v.* COTO BARK.

**HYDRO-*p*-COUMARIC ACID** *γ.* *p*-OXY-*β*-PHENYL-PROPIONIC ACID.

**HYDROCOUMARILIC ACID** *v.* COUMARILIC ACID.

**HYDROCOUMARIN** *v.* Anhydride of OXY-PHENYL-PROPIONIC ACID.

**HYDROCRONIC ACID** *v.* Hydride of CROCONIC ACID.

**HYDROCUMINOIN** *v.* CUMINOIN.

**HYDRO-*ψ*-CUMOQUINONE**  $C_{11}H_{10}(OH)_2$  [1:2:5:3:6]. [169°]. Formed by reducing *ψ*-cumoquinone (Nölting a. Baumann, *B.* 18, 1152). Needles (from water); sl. sol. cold, *v.* sol. hot, water.

**HYDROCYANALDINE** *v.* vol. i. p. 104.

**HYDROCYANIC ACID** *v.* CYANHYDRIC ACID, p. 300.

**HYDROFERRICYANIDES** *v.* FERRICYANIDES, p. 337.

**HYDROFERROCYANIDES** *v.* FERROCYANIDES, p. 333.

**HYDRO-FERULIC ACID** *v.* Methyl derivative of D<sub>2</sub>-OXY-PHENYL-PROPIONIC ACID.

**HYDROFLUOBORIC ACID** *v.* BOROFLOURHYDRIC ACID, vol. i. p. 526.

**HYDROFLUORIC ACID** *v.* FLUORHYDRIC ACID, p. 558.

**HYDROFLUOSILICATES** *v.* FLUOSILICATES, under SILICATES.

**HYDROGALLÉIN** *v.* GALLÉIN.

**HYDROGARDENIC ACID** *v.* GARDENIN.

**HYDROGEN** *H.* At. w. 1. Mol. w. 2. S.G. (air = 1) ·06926 (Regnault, at 0° and 760 mm. At sea-level latitude of Paris). Ratio of S.G. of *H* to that of *O* = 15·834 (Rayleigh, *N.* 37, 418; 39, 463). S.G. at 8,000 atmos. (water = 1) = ·0887 (Amagat, *C. R.* 107, 522). S.G. liquid at 0° = ·025, at -28° = ·032 (Caillaet a. Haube-fueille, *C. R.* 92, 1086). S.H.<sub>2</sub> 2·441 referred to equal weight of water; ·99 referred to equal volume of air; ratio of S.H.'s at constant pressure and constant volume 1·3852 (Clausius, *Mechan. Wärmetheorie*, 1, 62). C.E. (0° to 100°) ·0086678 (constant volume); ·0036615 (constant

pressure) (Regnault, *A. Ch.* [3] 5, 52). S (0° to 20°) ·0193; S. (alcohol at 0°) ·06925 (Bunsen, *Gasomet. Methoden*, 154).

Compressibility-coefficient 1000-1500 atmos. ·000408, 1500-2000 atmos. ·000272, 2000-2500 atmos. ·000197, 2500-3000 atmos. ·000158 (Amagat, *C. R.* 107, 522). On the compressibility of *H* for temperatures from -188° to +100° and pressures from 1 to 70 atmos. *v.* Wroblewski (*M.* 9, 1067; or *Nature*, 39, 588). H.C.P. [ $H_2O$ ] = 68,360 at c. 18°, product liquid  $H_2O$ ; [ $H_2O$ ] = 57,903 + 1·6 *t*, elements and product gaseous (Thomsen). Chief lines in emission-spectrum  $H\alpha$  6562·1,  $H\beta$  4860·7,  $H\gamma$  4339·3,  $H\delta$  4101·2 (Angström, *Spectre solaire*, Upsala, 1868).

The recognition of *H* as an individual gas was made by Cavendish in 1766. The name *hydrogen* was given by Lavoisier.

**Occurrence.**—In small quantities in the gases from volcanoes and fumaroles (Bunsen, *P.* 83, 167). In the gases issuing from the salt beds at Stassfurt (Reichardt, *Ar. Ph.* [2] 103, 347; Precht, *B.* 13, 2326); and at Wieliczka (H. Rose, *P.* 48, 353). Also condensed in certain meteorites (Graham, *Pr.* 15, 502; Mallet, *Pr.* 20, 365). In the intestines of several animals, produced by decomposition of organic material (Tappeiner, *B.* 14, 2375). Occurs also in the sun and many fixed stars. Compounds of *H* occur in large quantities; the chief compound is water; *H* is a constituent of almost all organic matter; compounds of *H* with Cl, S, and N also occur in fairly large quantities.

**Formation.**—1. By electrolysis of acidulated water.—2. By the reaction of many metals with  $H_2O$ ; K, Na, and other alkali metals decompose cold  $H_2O$  rapidly, forming hydroxides and *H*; Zn, Fe, Mg, Al, and many other metals decompose steam, forming oxides and *H*.—3. By passing steam over hot C,  $CO_2$  is also formed.—4. By heating  $CaO.H_2$ ,  $BaO.H_2$ ,  $NaOH$ , or  $KOH$ , with C;  $C + CaO + 2H_2O = CaCO_3 + 2H_2$ .—5. By the reactions of many metals with dilute solutions of acids, especially of  $HCl$  and  $H_2SO_4$ ;  $HNO_3$  cannot be used, as oxides of N are produced. 6. By heating  $KOHAq$  with Zn and Fe, or with Al, or Mg, or certain other metals.—7. By decomposing  $NH_3$  salts (not  $NH_4NO_3$ ) in solution by Zn; the action proceeds at c. 40° (Lorin, *C. R.* 60, 745).—8. By heating alkali formates or oxalates with  $KOH$ .

**Preparation.**—1. *Pure*, granulated zinc is placed in a capacious flask and a cold mixture of about 1 vol. *pure*  $H_2SO_4$  with c. 8 vols.  $H_2O$  is added. Addition of a little *pure*  $CuSO_4Aq$  prevents evolution of  $H_2S$  (by forming  $CuS$ ) which may be produced even with *pure* acid and Zn (Löwe, *D. P. J.* 214, 193). The contents of the flask must remain quite cold during the process; if temperature rises, traces of  $H_2S$  and  $SO$  begin to be evolved. The gas is passed through (1) conc.  $KMnO_4Aq$  to remove traces of  $AsH_3$ ,  $SbH_3$ , and  $PH_3$  (Schöbiel, *J. pr.* [2] 14, 289); (2) a U tube containing pumice soaked in  $AgNO_3Aq$  or  $HgCl_2Aq$  to remove the last traces of  $H_2S$ ,  $AsH_3$ , &c., the pumice should be first moistened with  $H_2SO_4$  and strongly heated in a crucible, to remove chlorides; (3) a U tube containing pumice or glass beads moistened with conc.  $KOHAq$  to remove any acid that may have been carried

over from the generating flask; (4) a series of tubes containing (a) dry  $\text{CaCl}_2$  in small lumps, (b) dehydrated, white  $\text{CuSO}_4$ , (c) a considerable length of  $\text{P}_2\text{O}_5$ . If the H is not required to be dry the last series of tubes will be omitted. If the H is to be used for reducing metallic oxides, &c., Winkler recommends to pass it through a red-hot tube packed with iron-wire gauze rolled together (B. 22, 896 note).—2. Pure KOHAq is heated with pieces of Al; the gas is passed through the same purifying tubes as 1, omitting the KOH tube.—3. By heating a mixture of  $\text{HCO}_2\text{K}$  and  $\text{KOH}$ , or  $\text{C}_2\text{O}_2\text{K}_2$  and  $\text{KOH}$ :  $2\text{HCO}_2\text{K} + 2\text{KOH} = 2\text{K}_2\text{CO}_3 + 2\text{H}_2$ ;  $\text{C}_2\text{O}_2\text{K}_2 + 2\text{KOH} = 2\text{K}_2\text{CO}_3 + \text{H}_2$  (cf. Pictet, *A.Ch.* [5] 13, 216).—4. By electrolyzing 10 p.c. pure  $\text{H}_2\text{SO}_4\text{aq}$ , the positive electrode being immersed in a mass of liquid Zn-amalgam (v. ANALYSIS, vol. i. p. 240).

**Properties.**—A colourless, tasteless, odourless, gas; liquefied under great pressure and at a very low temperature. Olzewski (C. R. 98, 913; 99, 183) liquefied H by surrounding the gas with N boiling *in vacuo*, the temperature of the N was  $-218^\circ$ ; the liquid H appeared as colourless drops on the sides of the tube. According to Olzewski the critical temperature of H is lower than  $-198^\circ$ ; Sarrau gives  $-174.2^\circ$  as the critical temperature (C. R. 94, 639; 718, 845). Wroblewski (M. 9, 1067) gives critical temperature  $-240^\circ$ ; critical pressure 13.5 atmospheres; and critical volume .00336. If these results are confirmed, they show that Pictet's statement that H is liquefied at  $-149^\circ$  is erroneous. Pictet (C. R. 86, 106) subjected H at c.  $-140^\circ$  to a pressure of 360 atmospheres; on opening the stopcock an opaque steel-blue jet issued; Pictet describes the fall of this jet on the floor as producing a sound like the rattling of shot. Jaillot obtained liquid H by suddenly reducing the pressure on the gas at 300 atmospheres (*A.Ch.* [5] 15, 132).

H is the lightest known substance; 1 litre at  $0^\circ$  and 760 mm. at the latitude of  $45^\circ$  weighs .08952289 gram (mean of results of Regnault [*Acad.* 21, 158] and Jolly [*W.* 6, 520]). H is about 14.4 times lighter than an equal volume of air, 11.160 times lighter than water, 151,700 times lighter than  $\text{Hg}$ , and 236,000 times lighter than Pt. H is only v. sl. sol. water. It diffuses rapidly through porous membranes, such as porcelain of paper; also through several metals at red heat (Graham, *Pr.* 15, 223; 16, 429; 17, 212, 500).

Large volumes of H are absorbed by Pd and several other metals, especially when the metal is made the negative electrode in the electrolysis of  $\text{H}_2\text{O}$ . Graham (*Pr.* 15, 502; 16, 422) found that Pd foil, which had been heated *in vacuo* occluded 876 vols. H at the ordinary temperatures, at  $90^\circ$ – $37^\circ$ , and 526 vols. at  $245^\circ$ . A Pd wire used as the negative electrode in electrolyzing water occluded 935 vols. H, and increased in length from 809.14 mm. to 818.91 mm. From such data Graham calculated the S.G. of the occluded H to be .733; later determinations by Dewar gave .62 (Z. M. [4] 47, 824). v. *infra* HYDROGENUM. According to Troost & Hautefeuille (C. R. 28, 968) Pd and H form a definite compound  $\text{Pd}_2\text{H}$ ; they think that this compound is formed when H is occluded by Pd, and the compound then continues to occlude or

absorb more H. T. a. H. heated the Pd which had occluded H in a closed space in connexion with a manometer, a portion of the H was evolved without establishment of any definite relation between the pressure and temperature, but when the H remaining was in the ratio  $\text{H}_2\text{Pd}$ , a definite relation was established between pressure and temperature, so that for each temperature there was a certain pressure whereat evolution of H ceased, and this pressure was independent of the relative masses of H and Pd. According to Favre (C. R. 77, 649; 78, 1257) for each gram of H occluded by Pd, about 9,000 gram-units of heat are produced. T. a. H. found that K and Na also occlude H, 1 vol. of K occluded 126 vols. H at c.  $360^\circ$ , the formula  $\text{K}_2\text{H}$  requires 124.6 vols. H. Na also seems to form a compound  $\text{Na}_2\text{H}$ . Li at  $500^\circ$  and 760 mm. occluded 17 times its volume of H; Ti only 3 times its volume. (For the dissociation-pressures of the compounds  $\text{Pd}_2\text{H}$ ,  $\text{K}_2\text{H}$ , and  $\text{Na}_2\text{H}$  v. DISSOCIATION, p. 398; for more details as to the properties of these bodies v. PALLADIUM, POTASSIUM, SODIUM.) Thoma has carefully investigated the absorption of H by metals (Z. P. C. 8, 69). He finds that Pd, made the negative electrode during electrolysis of water, takes up and retains a definite quantity of H; but that after this saturation-point is reached the Pd continues to absorb H, which, however, it readily gives up again; the total quantity of H absorbed depends on the strength of the current; when no more is taken up, it is very probable that H continues to be absorbed, but that as much is evolved as is absorbed in a given time; the increase in the volume of the Pd, for a given quantity of H absorbed, is greater when the saturation-point is passed than before it is reached, hence the relative density of what may be called the occluded H in excess is less than that of the H absorbed up to the saturation-point. Thoma has shown that Fe, like Pd, may be supersaturated with H, provided the H is produced in contact with the Fe. Plates or wires of Ni, and also Al, pyd. Cu, Cu wire, Pt black, Pt wire, and Ag wire, absorb H showing phenomena similar to Fe (Thoma, *l.c.*; Raoult, C. R. 1869, 826; Bellati & Lussana, *Atti del R. istituto veneto di Scienze, lettere ed arti*, 6, 6 [1888]).

H is a reducer; it removes O and most other negative elements from their compounds. Occluded H is a very active reducing agent;  $\text{KNO}_3\text{aq}$  is reduced to  $\text{KNO}_2\text{aq}$  (Böttger, B. 6, 1896); ferric salts are reduced to ferrous,  $\text{K}_2\text{FeCy}_3\text{aq}$  is reduced to  $\text{K}_2\text{FeCy}_4\text{aq}$  (Graham, *Pr.* 17, 500);  $\text{KClO}_4\text{aq}$  is reduced to  $\text{KClAq}$ ;  $\text{H}_2\text{CO}_3\text{aq}$  gives  $\text{H}_2\text{S}$ ,  $\text{As}_2\text{O}_3\text{aq}$  is reduced to As (Gladstone & Tribe, C. J. Trans. 1878, 808; cf. Berliner, W. 35, 791; also Cooke, C. N. 58, 103). The atomic weight of H is taken as unity; the relation between the atomic weights of H and O is very important as so many atomic weights are determined in terms of that of O. Various experiments have recently been made to determine the ratio of the densities of H and O directly; if this is known, and the ratio of the combining weights of these elements is also known, the ratio of the atomic weights of H and O will be directly determined. The most accurate determinations (which cannot, however, be regarded as final) give the ratio S.G. of H to S.G.

of  $O = 1:16:884$  (v. Rayleigh, *N.* 39, 462). The atom of H is the standard monovalent atom in terms of which the valencies of the other atoms are stated. The S.G. of gases is also generally stated in terms of H.

H is a combustible gas; it may be burnt in O, Cl, I, S vapour, &c.; if O is caused to flow from a narrow orifice into a quantity of H which has been ignited at the opening of the containing vessel, combination occurs at the edges of the moving stream, and hence the O appears to burn, and the H to act as the supporter of combustion. The flame of H is almost non-luminous; the temperature is very high.

*Hydrogenium.* This name was given by Graham to hydrogen when it is occluded by Pd (*Pr.* 17, 212, 500). The experiments of Graham, Dewar, Troost a. Hautefeuille, and Thoma, have shown that when H is occluded by Pd it is very much condensed (for references v. *supra*). Graham looked on H as a metal, and Pd charged with H is regarded as an alloy, hence to H alloyed with Pd he gave the name *hydrogenium* (names of metals generally end in *um*). There seems little doubt that a certain definite quantity of H is held by Pd in firmer union than the rest of the H which it is able to occlude (Thoma, *supra*).

*Reactions.*—1. H is burnt to  $H_2O$  by mixing with  $\frac{1}{2}$  its volume of oxygen, and applying a light or passing an electric spark; the process is explosive. The exact ratio of the volumes of H and O which combine cannot yet be regarded as settled; according to the experiments of Scott (*T.* 184, 543) the most probable value is  $O:H = 2:002:1$  (cf. WATER, vol. iv.).—2. H reduces many metallic oxides, sulphides, and chlorides; e.g.  $CuO$  and  $Fe_2O_3$  heated in H are reduced to Cu and Fe respectively;  $Sb_2S_3$  is reduced to Sb;  $FeCl_3$  is reduced to Fe.  $PdO$  is reduced at the ordinary temperature (Wöhler, *A.* 174, 60). Regarding the temperatures at which various oxides, sulphides, and chlorides are reduced by H v. Müller (*Z.* [2] 5, 507; also Wright a. Luff, *J. J. Trans.* 1878. 1). H also reduces many metallic salts in solution; e.g. warm solutions of chlorides of Pt, Pd, Ir, or Rh, are reduced with ppn. of the metals; some salts in solution are reduced only under considerable pressure, e.g.  $HgCl_2$  is reduced at 100 atmos. The reduction of  $AgNO_3$  by H proceeds very slowly at ordinary temperature (v. Russell, *C. J.* [2] 12, 3). As already stated (*supra*) Pd or Pt charged with H is a very energetic reducing agent. (Regarding the reaction of H and O in presence of CO v. CARBON, vol. i. p. 690.)

*Combinations.*—1. H combines indirectly with copper to form  $Cu_2H_2$  (v. COPPER HYDRIDE); it probably also combines with palladium, potassium, and sodium (v. *supra*).—2. H combines with all the non-metals; directly with O, N, O, S, Se, Te, F, Cl, Br, I; indirectly with P, As, Sb, Si, B (v. the various elements).

*Nascent hydrogen.*—Certain reductions not brought about by H are effected when a chemical change in which H is produced is carried out in presence of the body to be reduced; e.g.  $KClO_4$  is not reduced by passing H through the solution, but if Zn and dilute  $H_2SO_4$  are placed in the solution KCl is formed; so  $C_2H_5NO_2$  is not reduced by H under ordinary conditions, but if

Fe filings and dilute acid are brought into contact with  $C_2H_5NO_2$ , aniline ( $C_6H_5NH_2$ ) is formed. It is customary to speak of such reactions as those as brought about by *nascent hydrogen*. That the reduction of  $KClO_4$ , for instance, is not to be wholly traced to the H produced in contact with it is proved by the fact that Na-amalgam does not reduce this salt, although H is plentifully produced when Na-amalgam is placed in the solution (Tommasi, *P. B.* 2, 205). Nascent H is generally regarded as synonymous with atomic H, and it is contrasted with ordinary or molecular H. It is probable that H consists for the most part of atoms at the moment of its production from a compound, and that these then combine to form molecules. As energy must be degraded in the falling together of the atoms into molecules we should expect atoms of H to be capable of bringing about chemical changes that could not be accomplished by molecules of H. But the facts cited with regard to the reduction of  $KClO_4$ , and there are many similar facts, show that—granting that H is produced in atoms when Zn and  $H_2SO_4$ , or Na-amalgam and water, react—the whole of the chemical change must be looked to, and attention must not be concentrated only on the H. If we start with the system Zn,  $H_2SO_4$ ,  $KClO_4$ , we may pass to the system  $ZnSO_4$ ,  $H_2$ ,  $KClO_4$ , or to the system  $ZnSO_4$ ,  $KCl$ ,  $H_2O$ , or to a system which consists of all these products; more energy is probably degraded in passing to the third system than to any of the others; this system is produced. But this view does not hinder us from saying that when the Zn and  $H_2SO_4$  form  $ZnSO_4$  and hydrogen, it is atoms of H that are formed, and that some of these combine to form molecules, and others react with the  $KClO_4$  to form  $KCl$  and  $H_2O$ . In the case of Na-amalgam and  $KClO_4$  it is probable that much more energy is degraded in passing to the system  $NaOH$ ,  $H_2$ ,  $Hg$ ,  $KClO_4$ , than to the system  $NaOH$ ,  $Hg$ ,  $KCl$ ,  $H_2O$ . Probably also in the case of Zn and  $H_2SO_4$  the energy produced suffices to decompose some of the  $KClO_4$ , and so  $KCl$  and  $H_2O$  are formed; whereas the energy produced in the reaction of Na-amalgam with  $H_2O$  is not (by hypothesis) sufficient to decompose any  $KClO_4$ .

*Chemical relations of hydrogen.*—H stands apart from the other elements. In its relations to O, Cl, S, and other negative elements, it plays the part of a metal; in its relations to the paraffins  $C_nH_{2n+2}$ , and paraffin alcoholic radicles  $C_nH_{2n+1}$ , it exhibits properties not at all characteristic of metals. H is a constituent of all acids, and also of all alkalis. Some of the binary compounds of H are powerful acids, some are alkalis, some are neutral bodies. In the periodic arrangement of the elements H is placed as the only member of series 1. The difference between the atomic weights of two consecutive members of the same group, in odd and even series, is about 2; the difference between the atomic weight of H and that of Li, which follows H in Group 1, is 6.

Hydrogen nitride v. AMMONIA, vol. i. p. 196.

Hydrogen oxides. Two oxides of hydrogen are known,  $H_2O$  and  $H_2O_2$ . The former has been gasified, and its molecular composition is represented by the formula  $H_2O$ ; the latter is decomposed by heat, the gaseous molecule  $H_2O_2$  cannot exist, therefore the formula  $H_2O_2$  represents the composition of the chemically reacting atomic aggregate of this compound. Water is a stable compound; in its chemical relations it is a neutral oxide; its typical reaction with a metal is to produce an oxide and  $H$ , its typical reaction with a non-metal is to produce a hydride and  $O$ . Hydrogen peroxide readily parts with  $\frac{1}{2}$  of its  $O$ , and therefore acts generally as an oxidiser. Water combines with many compounds and with some elements to form hydrates, with other compounds and elements it reacts to form hydroxides (v. HYDRATES and HYDROXIDES, pp. 708, 733); hydrogen peroxide directly combines with but few other bodies.

HYDROGEN MONOXIDE OF WATER, v. WATER, in vol. iv.

HYDROGEN DIOXIDE  $H_2O_2$ . (*Hydrogen peroxide*. *Oxygenated water*. Sometimes also called *hydroxyl*, but this term is now almost universally retained for the radicle  $OH$ .) This compound was first prepared by Thénard in 1818. (Thénard's chief memoirs are contained in *A. Ch.* 8, 306; 9, 51, 94, 314; 414; 10, 114, 335; 11, 85, 205; 50, 80.)  $H_2O_2$  has not been obtained quite free from water.

*Occurrence*.—In rain-water and snow (Struve, *Z.* [2] 5, 274; Houzeau, *C. R.* 70, 519; cf. ARCSPHERE, vol. i. p. 333). According to Clermont (*C. R.* 80, 1591)  $H_2O_2$  occurs in the juices of tobacco plants, vines, and lettuces; Wurster (*B.* 19, 3195) asserts the occurrence of  $H_2O_2$  in many animal and vegetable secretions; but Bokorny (*B.* 21, 1100) points out that his test was inconclusive.

*Formation*.—1. By decomposing various peroxides by dilute acids, e.g.  $BaO_2$  by  $H_2SO_4$ aq,  $HCl$ aq,  $CO_2$ aq, or  $H_2SiF_6$ aq, or  $K_2O_2$  by tartaric acid (v. Thénard, l. c.; Duprey, *J. pr.* 88, 440; Schönbein, *J. pr.* 77, 263; Osann, *C. C.* 1862, 97; v. Hoffmann, *A.* 136, 188).—2. By shaking  $Zn$  or  $Fe$  powder with water in presence of air (Schönbein, *J. pr.* 105, 219; Hoppe-Seyler, *H.* 2, 25; 10, 86).—3. By the action of hydrogenised  $Pd$  on water in presence of  $O$  (Traube, *B.* 15, 659, 2434, 2451; 16, 1201).—4. During the electrolysis of fairly conc.  $H_2SO_4$ aq; dilute  $H_2SO_4$  gives little or no  $H_2O_2$ . Richards (*W.* 31, 512)

says that 70 p.c. acid is the best concentration w use. Much work has been done on the source of  $H_2O_2$  in the electrolysis of  $H_2SO_4$ aq. Richards (*loc. cit.* W. 24, 183) regards the  $H_2O_2$  as a product of the reaction of  $H_2S_2O_8$  (formed by electrolysis) and  $H_2O$ ; when 68 p.c.  $H_2SO_4$ aq is used, the amount of  $H_2O_2$  increases, and then becomes constant, but the  $H_2S_2O_8$  goes on increasing, on stopping the current  $H_2O_2$  increases for a time, and  $H_2S_2O_8$  notably decreases. In a solution containing  $H_2SO_4$  and  $H_2S_2O_8$ , the latter slowly disappears, and  $H_2O_2$  is produced. Traube holds that the  $H_2O_2$  is directly produced by the reaction of ordinary (molecular)  $O$  with water and nascent  $H$  (*loc. cit.* B. 19, 1111; 20, 3345). The  $H_2O_2$  is always formed at the negative electrode.—5. According to Berthelot (*C. R.* 86, 71)  $H_2O_2$  is formed by shaking  $O_2$  with ether, and then adding water.—6. By the oxidation of very dilute  $NH_4$ aq by ozonised  $O$  [ $2NH_4$ aq +  $2O$  =  $NH_4NO_2$ aq +  $H_2O_2$ ] (Carins, *B.* 7, 1481).—7. By placing a solution of pyrogallol under a bell jar (Struve, *W. A. B.* 68 [2nd part], 432).—8. By burning  $H$  in air (Struve, *J.* 1870, 109, 209).—9. By shaking various essential oils containing terpenes with water in presence of air (Schönbein, *J. pr.* 99, 11; Radenowitsch, *B.* 6, 1208; Kingzett, *C. J.* [2] 13, 210).—10. During many processes of oxidation in presence of water (v. Schönbein, *J. pr.* 89, 14; 98, 257).

*Preparation*.—By decomposing  $BaO_2$  by dilute acids.—1. Thénard prepared  $BaO_2$  by heating  $BaO$  in small pieces to low redness in a stream of  $O$  free from  $CO_2$ ; the  $BaO$  was obtained by strongly heating  $Ba(NO_3)_2$ ; the stream of  $O$  was maintained for fifteen minutes after  $O$  had apparently ceased to be absorbed. (For method of preparing pure  $BaO_2$  v. vol. i. p. 443.) The  $BaO_2$  was allowed to cool in  $O$ , and then placed in a stoppered bottle. 200 grams  $H_2O$  were then mixed with sufficient  $HCl$  to neutralise about 15 grams  $BaO_2$ ; this dilute  $HCl$ aq was placed in a Pt vessel surrounded by ice, and 12 grams  $BaO_2$ , slightly moistened and rubbed to powder in an agate mortar, were added; the  $Ba$  was then ppt. by  $H_2SO_4$ aq; 12 grams  $BaO_2$  were again added, and the  $Ba$  was again removed; the liquid was filtered, and addition of  $BaO_2$  in two portions, with pptn. by  $H_2SO_4$ aq, was repeated. These processes were repeated until about 100 grams  $BaO_2$  had been used.  $SiO_2$ ,  $Al_2O_3$ ,  $Fe_2O_3$ , &c., were removed by adding conc.  $H_3PO_4$ aq and excess of  $BaO_2$ . After rapid filtration traces of  $HCl$  were separated by cautious addition of powdered  $Ag_2SO_4$  to the liquid surrounded by ice. After another rapid filtration  $H_2SO_4$ aq was removed by addition either of  $BaO_2$  suspended in water, or of ppt.  $BaCO_3$ .—2. Pelouze (v. *Berzelius' Lehrbuch*, 1, 411) decomposed  $BaO_2$  by  $H_2SiF_6$ aq, the liquid being kept cold, and filtered from  $BaSiF_6$ .

3. Thomsen (*B.* 7, 73) dissolves finely-powdered  $BaO_2$  in dilute  $HCl$ aq until the acid is nearly neutralised; after filtration the liquid is cooled, and  $BaO$ aq is added sufficient to ppt.  $SiO_2$ ,  $Al_2O_3$ , and other oxides, and to produce a slight ppt. of  $BaO_2 \cdot 8H_2O$ ; the liquid is again filtered and mixed with conc.  $BaO$ aq, whereby crystalline  $BaO_2 \cdot 8H_2O$  is ppt.; this moist ppt. may be kept unchanged in a stoppered bottle. Thomsen decomposes the moist  $BaO_2 \cdot 8H_2O$  by

Adding it to cold dilute  $\text{H}_2\text{SO}_4$  (not more conc. than 1 part by weight  $\text{H}_2\text{SO}_4$  to 5 parts  $\text{H}_2\text{O}$ ) with constant stirring, until the acid is nearly neutralised; after settling and filtering, he ppts. the remaining acid by cautious addition of dilute  $\text{BaOAc}$ .

4. Mann (*Chemiker Zeitung*, 12, 857) recommends to add a  $\frac{1}{2}$  p.c.  $\text{H}_3\text{PO}_4$  to commercial  $\text{H}_2\text{O}_2$ , and then, while stirring vigorously, to add  $\text{BaO}_2$  until exactly neutral to litmus; then to pour the clear liquid into cold conc.  $\text{BaOAc}$ , to wash the ppd.  $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$ , and to decompose it by dropping into cold dilute  $\text{H}_2\text{SO}_4$  containing 12 p.c.  $\text{H}_2\text{SO}_4$ , removing any excess of acid by dilute  $\text{BaOAc}$  (v. also Schöne, A. 192, 252).

The solution of  $\text{H}_2\text{O}_2$  obtained by one or other of these methods is concentrated *in vacuo* over  $\text{H}_2\text{SO}_4$  with agitation from time to time; if  $\text{SiO}_2$  separates it must be removed, else it will decompose some of the  $\text{H}_2\text{O}_2$ . The liquid begins to give off O when it is so conc. that one volume of it will yield about 250 vols. O, a drop or two of  $\text{H}_2\text{SO}_4$  is then added, and evaporation is continued. Nearly pure  $\text{H}_2\text{O}_2$  is thus obtained. 1 vol. will give 475 vols. O. It is kept in stoppered glass tubes surrounded by ice (Thénard). Hanriot (*C. R.* 100, 172) concentrates  $\text{H}_2\text{O}_2$  by distillation under reduced pressure; a solution, 1 vol. of which will give 267 vols. O, can thus be obtained. A solution so conc. that 1 vol. yields c. 70 vols. O is obtained by freezing dilute  $\text{H}_2\text{O}_2$  Acq, crystals of pure  $\text{H}_2\text{O}$  separate (Hanriot, *C. R.* 100, 57).

**Properties.**—The most conc. solution of  $\text{H}_2\text{O}_2$  obtained as described under *Preparation* is a syrupy liquid S.G. = 1.453; it does not freeze at  $-80^\circ$ ; *in vacuo* it volatilises unchanged (Thénard). Has a harsh bitter taste; corrodes the cuticle. Thomsen gives the thermal data:  $[\text{H}^+\text{O}^-\text{Acq}] = 45,800$ ;  $[\text{H}^+\text{O}_2\text{Acq}] = -23,060$ ;  $[\text{H}^+\text{O}^-\text{Acq}, \text{H}^+] = 91,420$  (*Th.* 2, 59); Berthelot gives  $[\text{H}^+\text{O}^-\text{Acq}] = 45,800$ ;  $[\text{H}^+\text{O}_2\text{Acq}] = -23,060$ ;  $[\text{H}^+\text{O}^-\text{Acq}, \text{H}^+] = 91,420$  (*A. Ch.* [5] 6, 209). According to Hanriot (*Bl.* [2] 43, 468) conc.  $\text{H}_2\text{O}_2$  Acq has an acid reaction towards turmeric, and an odour resembling that of nitric acid.  $\text{H}_2\text{O}_2$  Acq slowly decomposes; if very dilute it may be kept indefinitely (Berthelot, *C. R.* 90, 897); very dilute solutions may even be boiled without change (Hanriot, *C. R.* 100, 57). Traces of impurities greatly modify the stability of  $\text{H}_2\text{O}_2$  Acq; acids increase, alkalis decrease, the stability. Very conc.  $\text{H}_2\text{O}_2$  Acq rapidly evolves O at  $20^\circ$ ; heated quickly to  $100^\circ$  O is evolved with explosion; 1 vol. of the most conc. solution obtained by Thénard gave 475 vols. O at  $0^\circ$  and 760 mm. It is customary to state the conc. of commercial  $\text{H}_2\text{O}_2$  Acq as so many volumes, e.g. '20 volumes'; this means that 20 volumes O are obtainable from 1 vol. of the solution.  $\text{H}_2\text{O}_2$  is soluble in all proportions in water, also in alcohol; but it slowly reacts with the alcohol; in sol. ether. On shaking this solution with water the  $\text{H}_2\text{O}_2$  all goes into solution in the water (Schönbein, *J. pr.* 78, 92). An acidified solution of  $\text{H}_2\text{O}_2$  is decomposed to H and O by electrolysis. According to Schöne (*A.* 197, 137), the  $\text{H}_2\text{O}_2$  does not undergo electrolysis, but is decomposed by reacting with the products of electrolysis of the dilute acid present, probably (i.)  $\text{H}_2\text{O}_2 + \text{O} = \text{H}_2\text{O} + \text{O}_2$  (ii.)  $\text{SO}_2 + \text{H}_2\text{O}_2 = \text{H}_2\text{SO}_4 + \text{O}_2$  (iii.)  $\text{H}_2 + \text{H}_2\text{O}_2 = 2\text{H}_2\text{O}$ .

**Reactions.**— $\text{H}_2\text{O}_2$  contains a larger percentage of O (94.1 p.c.) than any other compound; it readily parts with  $\frac{1}{2}$  of its O, and therefore reacts as an oxidiser; in some cases, however, it acts as a reducer, e.g.  $\text{Ag}_2\text{O}$  is reduced to Ag and  $\text{PbO}_2$  to  $\text{PbO}$  (v. *infra*).

1. Aluminium, iron, magnesium, and thallium are oxidised to the hydrates  $\text{FeO} \cdot \text{H}_2\text{O}$ ,  $\text{AlO} \cdot \text{H}_2\text{O}$ ,  $\text{MgO} \cdot \text{H}_2\text{O}$ , and  $\text{TlO} \cdot \text{H}_2\text{O}$ , according to Weltzien (*A.* 138, 129).—2. Most metals except Au and the Pt metals are changed to oxides. 3. Several non-metals are oxidised, generally to their highest oxides, e.g. Se and As.—4. Very many oxides and oxyacids are converted into more oxidised compounds, e.g.  $\text{Ag}_2\text{O}$  to  $\text{Ag}_2\text{O}_2$ ,  $\text{H}_3\text{PO}_3$  to  $\text{H}_3\text{PO}_4$ ,  $\text{CaO}$ ,  $\text{SrO}$ , and  $\text{BaO}$  to the dioxide  $\text{MO}_2$ , ferrous to ferric compounds,  $\text{PbS}$  to  $\text{PbSO}_4$ ,  $\text{TiO}$  to  $\text{Ti}_2\text{O}_3$  (v. Schöne, A. 196, 98),  $\text{K}_2\text{FeCy}_4$  to  $\text{K}_2\text{FeCy}_6$  (Weltzien, A. 138, 129). Several metallic salts yield peroxides when treated with  $\text{H}_2\text{O}_2$  in presence of ammonia, e.g. salts of Bi, Ce, Co, Ni.—5. Sulphuretted hydrogen very slowly forms  $\text{H}_2\text{O}$  and S (Fairley, *C. J.* [2] 16, 23).—6. Hydrogen iodide forms  $\text{H}_2\text{O}$  and I.—7. A solution of chromic hydrate in potash is oxidised by  $\text{H}_2\text{O}_2$  to  $\text{K}_2\text{CrO}_4$  (cf. Reaction 11 *infra*).—8. Ammonia in solution is oxidised to  $\text{NH}_4\text{NO}_3$  [ $4\text{NH}_3\text{Acq} + 6\text{H}_2\text{O}_2 = 2\text{NH}_4\text{NO}_3\text{Acq} + 8\text{H}_2\text{O}$ ] (Weith a. Weber, B. 7, 1746).—9. According to Fairley (*C. J.* [2] 16, 125) the unstable compound  $\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$  is formed by adding alcohol to a mixture of equivalent weights of  $\text{H}_2\text{O}_2$  and caustic soda (v. also Schöne, A. 192, 241). Caustic potash reacts somewhat differently, giving a mixture of  $\text{K}_2\text{O}$  with  $\text{KOH} \cdot x\text{H}_2\text{O}$  (Schöne, 2c.).

10.  $\text{H}_2\text{O}_2$  reduces ozone, forming  $\text{H}_2\text{O}$  and oxygen. Brodie (T. 1850, 759) showed that  $\frac{1}{2}$  of the O comes from the ozone and  $\frac{1}{2}$  from the  $\text{H}_2\text{O}_2$ ; this result was confirmed by Schöne (A. 196, 239); Schöne used neutral solutions of  $\text{H}_2\text{O}_2$ , Brodie used alkaline solutions.—11. Several metallic peroxides are reduced by  $\text{H}_2\text{O}_2$  in presence of acid. For instance  $\text{CrO}_5$  in  $\text{H}_2\text{SO}_4$  solution gives a blue colour, but this soon goes, and green  $\text{Cr}_2\text{SO}_4$  is produced (cf. Reaction 7 *supra*); Berthelot thinks that perchromic acid  $\text{HCrO}_5$  is formed and then reduced by the excess of  $\text{H}_2\text{O}_2$ ; Moissan regards the blue body as  $\text{CrO}_5 \cdot \text{H}_2\text{O}_2$  (v.  $\text{CrO}_5$  under *Oxides*, p. 166); MnO, in presence of an acid forms a salt of MnO and evolves O; for every MnO, used, O<sub>2</sub> is evolved (cf. Reaction 19 *infra*). Brodie showed that in such cases  $\frac{1}{2}$  of the O evolved comes from the  $\text{H}_2\text{O}_2$ , and  $\frac{1}{2}$  from the metallic peroxide (*C. J.* 4, 194; 7, 894; cf. Aschoff, *J. pr.* 81, 401). According to Lenssen (*J. pr.* 81, 278)  $\text{H}_2\text{O}_2$  oxidises metallic oxides in presence of alkalis when the alkali can combine with the higher oxide produced by the  $\text{H}_2\text{O}_2$ , to form a salt—e.g.  $\text{Cr}_2\text{O}_3$  to  $\text{CrO}_5$  in presence of  $\text{KOH}$ —but it reduces higher to lower oxides in presence of acids when the acid forms a stable salt with the lower oxide, e.g.  $\text{CrO}_5$  to  $\text{Cr}_2\text{O}_3$  in presence of  $\text{H}_2\text{SO}_4$ . 12. Potassium dichromate is reduced by  $\text{H}_2\text{O}_2$  in neutral solutions to  $\text{CrO}_3$ , in acid solutions to a salt of  $\text{Cr}_2\text{O}_3$  (Schönbein, *J. pr.* 70, 357; Aschoff, *J. pr.* 81, 401).—13. Potassium permanganate in presence of  $\text{H}_2\text{SO}_4$  is reduced to  $\text{MnSO}_4$ , thus  $2\text{KMnO}_4\text{Acq} + 5\text{H}_2\text{O}_2 + 3\text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4\text{Acq} + 2\text{MnSO}_4\text{Acq} + 8\text{H}_2\text{O} + 5\text{SO}_4$ . In this case also  $\frac{1}{2}$  of the O comes from the  $\text{H}_2\text{O}_2$ , and  $\frac{1}{2}$

from the  $\text{KMnO}_4$ . According to P. Thénard (*C. R.* 76, 177)  $\text{H}_2\text{O}_2$  and  $\text{KMnO}_4$  react when kept at a low temperature, but no O is evolved; Berthelot (*C. R.* 90, 656) confirms this, he thinks an oxide  $\text{H}_2\text{O}_2 \cdot x\text{O}$  is formed.—14. *Sulphur oxide*,  $\text{Ag}_2\text{O}$ , is reduced to Ag by  $\text{H}_2\text{O}_2$ ;  $\text{Ag}_2\text{O} + \text{H}_2\text{O}_2 = \text{H}_2\text{O} + \text{O}_2 + 2\text{Ag}$ ; HgO reacts similarly. Berthelot (*C. R.* 90, 572) thinks that an oxide  $\text{Ag}_2\text{O}$  is produced.—15. According to Harriott (*Bl.* [2] 43, 468)  $\text{H}_2\text{O}_2$  reduces Fehling's solution.—

16.  $\text{H}_2\text{O}_2$  reacts with chlorine to form HCl and O;  $\text{H}_2\text{O}_2 + \text{Cl}_2 = 2\text{HCl} + \text{O}_2$ . Schöne (*A.* 196, 254) thinks the reactions may be  $\text{H}_2\text{O}_2 + \text{OH}_2 + \text{Cl}_2 = \text{H}_2\text{O} + \text{O}_2 + 2\text{HCl}$ .—17. *Iodine* forms HI and O, by reacting with dilute  $\text{H}_2\text{O}_2$  Aq; but HI decomposes more conc.  $\text{H}_2\text{O}_2$  Aq to form  $\text{H}_2\text{O}$  and I. In the reaction between I and  $\text{H}_2\text{O}_2$ , an oxyacid of I may be produced and then decomposed; when I is added to KOHAq containing  $\text{H}_2\text{O}_2$ , only KI is formed (no  $\text{KIO}_3$ ) and O is evolved (cf. Fairley, *C. J.* [2] 16, 22).

$\text{H}_2\text{O}_2$  is decomposed to  $\text{H}_2\text{O}$  and O by several substances which at the close of the reaction remain the same as they were at the beginning.

18. *Platinum, gold, silver, and charcoal*, added to  $\text{H}_2\text{O}_2$ , cause evolution of O and formation of  $\text{H}_2\text{O}$ . Fibrin and some other organic substances bring about the same change.

19. *Manganese dioxide* added to  $\text{H}_2\text{O}_2$  produces O and  $\text{H}_2\text{O}$ , and the same quantity of  $\text{MnO}_2$  remains as was originally added (for action when an acid is present v. Reaction 11 *supra*).

20. *Potassium iodide* with pure  $\text{H}_2\text{O}_2$  Aq causes evolution of O, but no I is liberated (Kingzett, *C. J.* 37, 806; Schöne, *A.* 195, 228). Schöne supposes that a series of changes occurs, possibly the K salt of an oxyacid (? hypiodite) is formed and then reacts with more  $\text{H}_2\text{O}_2$ , to give KI,  $\text{H}_2\text{O}$ , and O. Ordinary commercial  $\text{I}_2\text{O}_5$  Aq liberates I from KI.—21. *Potassium permanganate and chloride* both cause evolution of O; (Br more slowly than KI, and KCl more slowly than KBr; no Br or Cl is liberated (Schöne, *l.c.*).

22. *Certain salts*, e.g.  $\text{V}_2\text{O}_5$ , also decompose  $\text{I}_2\text{O}_5$ , but the salt is the same at the close as at the beginning of the reaction (v. Schöne, *l.c.*).

23. The *caustic alkalis* decompose  $\text{H}_2\text{O}_2$  with formation of O and  $\text{H}_2\text{O}$ ; Schöne has examined these reactions; he thinks that the first products are  $\text{H}_2\text{O}$  and compounds  $\text{M}_2\text{H}_2\text{O}_2$  (M = alkali metal), these compounds have been isolated (v. *Combinations, infra*); these compounds then decompose to alkali,  $\text{H}_2\text{O}$ , and O. Schöne shows that the rate at which  $\text{H}_2\text{O}_2$  is decomposed by alkalis is modified by temperature, light, concentration, traces of impurities, and the condition of the surfaces of the containing vessels.

$\text{H}_2\text{O}_2$  is a representative peroxide; its reactions are similar to those of  $\text{BaO}_2$ ,  $\text{SrO}_2$ , &c., and the organic peroxides such as acetyl peroxide ( $\text{C}_2\text{H}_5\text{O}_2$ ); it cannot be said to have distinctly basic or acidic properties, but on the whole it is more acidic than basic, e.g. in the reaction  $\text{BaO}_2 \cdot \text{H}_2\text{SO}_4 + \text{H}_2\text{O}_2 = \text{BaO}_2 \cdot \text{SO}_4 + 2\text{H}_2\text{O}$  there is probably an exchange of the H of  $\text{H}_2\text{O}_2$  for the metal Ba.

*Combinations*.—Schöne (*A.* 192, 257) has obtained bodies which are probably compounds of  $\text{H}_2\text{O}_2$  with the peroxides of the alkali and alkaline earth metals. When 1 equiv. KOH in

solution was added to about 8 equiv.  $\text{H}_2\text{O}_2$ , the liquid was evaporated *in vacuo* and the residue dried at  $-10^\circ$ , a white solid  $\text{K}_2\text{O}_2 \cdot 2\text{H}_2\text{O}_2$  ( $= \text{K}_2\text{H}_4\text{O}_6$ ) was obtained. Using about the same proportions of NaOH and  $\text{H}_2\text{O}_2$ , the compound  $\text{Na}_2\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$  ( $= \text{Na}_2\text{O}_2 \cdot 2\text{H}_2\text{O}_2 \cdot 4\text{H}_2\text{O}$ ) was obtained. Both these compounds are easily decomposed by warming with evolution of O. The compound  $\text{BaO}_2 \cdot \text{H}_2\text{O}_2$  was obtained by direct addition of its constituents, or by adding a certain quantity of  $\text{NH}_4\text{Aq}$  to a Ba salt solution in presence of  $\text{H}_2\text{O}_2$ ; this compound is very unstable, it easily goes to  $\text{BaO}_2$ ,  $\text{H}_2\text{O}$ , and O; if the decomposition is effected by warming under water, crystals of  $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$  are formed. Indications of the existence of compounds of  $\text{H}_2\text{O}_2$  with CaO and  $\text{SrO}_2$  were obtained, but the compounds could not be isolated on account of their great instability.

*Detection and Estimation*.— $\text{H}_2\text{O}_2$  Aq produces a blue colour in a dilute solution of guaiacum mixed with an infusion of malt. Addition of a few drops of Pb acetate solution, followed by KIAq and starch and a little acetic acid, produces a blue colour (Schönbein, *J. pr.* 86, 129; Struve, *Z.* 1869, 274). Bicharz (*W.* 31, 912) says the best reagent for detecting  $\text{H}_2\text{O}_2$ , especially in presence of  $\text{S}_2\text{O}_3$ , is a solution of titanous acid in  $\text{H}_2\text{SO}_4$ ; a very yellow pp. is obtained; this pp. decolorises the same quantity of  $\text{KMnO}_4$  Aq as the  $\text{H}_2\text{O}_2$  in the solution from which the pp. was obtained (cf. Schönbein, *Er.* 9, 21, 330; D. P. J. 210, 317).

According to Harriott (*Bl.* [2] 43, 468)  $\text{H}_2\text{O}_2$  is best estimated by measuring the amount of O liberated by reacting with  $\text{MnO}_2$ . It may also be estimated by measuring the quantity of  $\text{KMnO}_4$  reduced, or the O liberated by reacting with  $\text{KMnO}_4$  Aq; Kingzett (*C. J.* 37, 806) says no acid should be present: the reaction is  $2\text{KMnO}_4 + 3\text{H}_2\text{SO}_4 + 5\text{H}_2\text{O}_2$

KIAq may be brought into contact with  $\text{H}_2\text{O}_2$  Aq, and the I estimated by dilute standard  $\text{Na}_2\text{S}_2\text{O}_3$  Aq; best in presence of much dilute  $\text{H}_2\text{SO}_4$  Aq (Kingzett, *l.c.*; cf. Schöne, *B.* 7, 1696; Hamel, *C. E.* 76, 1023).

*Hydrogen phosphides* v. PHOSPHORUS, HYDRIDES or.

*Hydrogen selenide*  $\text{H}_2\text{Se}$ . (*Seleniethydride* or *seleniuretted hydrogen*. *Selenhydric acid*. *Hydro-selenic acid*. *Selenion hydride*.) Mol. w. 80.8. This compound is the Se analogue of  $\text{SH}_2$ .

*Formation*.—1. By leading H over Se heated to c.  $400^\circ$ – $500^\circ$  (Corenwinder, *A. Ch.* [3] 84, 77; Wöhler u. Uelsmann, *A.* 116, 122); or by heating H and Se in a closed tube to c.  $440^\circ$  (Hautefeuille, *C. R.* 64, 608). According to Ditté (*J. R.* 74, 980) combination of H and Se begins at c.  $250^\circ$ , is at its maximum at c.  $520^\circ$ , and then decreases to  $750^\circ$ , where it ceases.—2. By the action of Se on  $\text{H}_2$  gas at the ordinary temperature (Hautefeuille, *Bl.* [2] 7, 198); in presence of water, however,  $\text{SeH}_2$  and I give Se and HI. According to Hautefeuille (*C. R.* 68, 1554)  $\text{SeH}_2$  and I are produced by heating Se with fairly conc. HIAq in a sealed tube, but on cooling Se crystallises and HIAq remains.—3. By the action of water on Se phosphide ( $\text{P}_2\text{Se}_3 + 4\text{H}_2\text{O} = 2\text{H}_3\text{PO}_3 + 6\text{H}_2\text{Se}$ ). Berzelius recommends this as the best method for pre-

paring  $\text{H}_2\text{Se}$  (*Lehrbuch* [5th ed.], 2, 211).—4. By treating  $\text{FeSe}$  (obtained by strongly heating  $\text{Fe}$  with  $\text{Se}$ ) with fairly diluted  $\text{HClAq}$  (v. Divers a. Shimidzu, *C. J.* 47, 441).

**Properties.**—A colourless gas with most irritating odour, resembling that of  $\text{SH}_2$  and  $\text{Cl}$  combined. Extremely poisonous. A minute quantity of the gas inhaled removes the sense of smell for a time, and produces violent headache. In working with this compound great precautions must be taken. Berzelius thus describes the effect of allowing a bubble of the gas to pass into his nostrils: 'Bei meinem ersten Versuche, den Geruch dieses Gases kennen zu lernen, hatte ich, als eine Gasblase, vielleicht nicht grösser als eine Erbse, in eines der Nasenlöcher gelangt war, für mehrere Stunden so gänzlich den Geruch verloren, dass ich ohne das geringste Gefühl das stärkste Ammoniak unter die Nase halten konnte. Der Geruch kam nach fünf bis sechs Stunden wieder, aber ein sehr heftiger und beschwerlicher Schnupfen hielt vierzehn Tage lang an' (*Lehrbuch* [5th ed.], 2, 213).  $\text{SeH}_2$  is more soluble in water than  $\text{SH}_2$ ; the solution reddens litmus; it quickly decomposes in air with ppn. of  $\text{Se}$ .

**Reactions.**—1. Heat decomposes  $\text{SeH}_2$  into  $\text{Se}$  and  $\text{H}$ . Ditte (*C. R.* 74, 986) says that the change begins at  $150^\circ$ , is considerable at  $270^\circ$ , but then decreases until it reaches a minimum at  $520^\circ$ , after which it again increases; if  $\text{H}$  is passed over  $\text{Se}$  heated to  $c. 600^\circ$   $\text{SeH}_2$  is formed, but is again decomposed on coming into the colder part of the tube, so that crystals of  $\text{Se}$  are formed on those parts of the tube. Ditte's results would show that the dissociation-pressure of  $\text{SeH}_2$  does not increase regularly with increase of temperature (v. remarks on the action of heat on  $\text{SeH}_2$  under DISSOCIATION, p. 398).—2. Moist air causes decomposition of  $\text{SeH}_2$  with separation of  $\text{Se}$ .—3. Electric sparks cause separation into  $\text{Se}$  and  $\text{H}$  (Berthelot, *B.* [2] 26, 101).—4. Many metals decompose  $\text{SeH}_2$  when heated in it; by heating with  $\text{Sn}$  a volume of  $\text{SeH}_2$  gives its own volume of  $\text{H}$ .—5. Towards metallic oxides and salts  $\text{SeH}_2$  acts very similarly to  $\text{SH}_2$ ; it ppt. selenides from solutions of many salts.—6. Dilute sulphurous acid reacts with excess of  $\text{H}_2\text{Se}$  to form  $\text{Se}$  and a little  $\text{SH}_2$ ; the reactions probably are (1)  $2\text{SeH}_2 + \text{H}_2\text{SO}_3\text{Aq} = 2\text{Se} + \text{S} + 3\text{H}_2\text{OAq}$ , (2)  $\text{SeH}_2\text{Aq} + \text{S} = \text{SH}_2\text{Aq} + \text{Se}$  (Divers a. Shimidzu, *C. J.* 47, 441). When  $\text{H}_2\text{Se}$  gas is passed into  $\text{SO}_2\text{Aq}$  a pp. is formed containing both  $\text{S}$  and  $\text{Se}$ , probably a seleno-thionio acid (D. a. S., *l.c.*).—7. When  $\text{H}_2\text{Se}$  is brought into contact with sulphur  $\text{H}_2\text{S}$  and  $\text{Se}$  are at once produced (D. a. S., *l.c.*).

Hydrogen silicide  $\text{SiH}_2$  v. SILICON HYDRIDE in vol. iv.

**Hydrogen sulphides of.** Two sulphides of  $\text{H}$  are known,  $\text{H}_2\text{S}$  corresponding with  $\text{H}_2\text{O}$ , and a persulphide  $\text{H}_2\text{S}_2$  probably corresponding with  $\text{H}_2\text{O}_2$ . The sulphide  $\text{H}_2\text{S}$  in solution acts as a weak acid; the persulphide is generally analogous in its reactions to  $\text{H}_2\text{O}_2$ .

**HYDROGEN SULPHIDE  $\text{H}_2\text{S}$ .** (*Hydrogen monosulphide. Sulphuretted hydrogen. Sulphydric acid. Hydrosulphuric acid. Hydrothionio acid.*) Mol. w. 34.06. [ $\alpha. -85.5^\circ$ ] (Faraday, *T.* 1845, 1, 155). [ $\alpha. -61.6^\circ$  at 760 mm.] (Regnault, *Acad.* 56, 568). V.D. 8. S.G. Liquid g. 9. S.H.p.

$-242.3^\circ$  (Croullebois, *A. Ch.* [4] 20, 136). S. at  $5^\circ$  3.96, at  $15^\circ$  3.23, at  $20^\circ$  2.9, at  $25^\circ$  2.6, at  $30^\circ$  2.38, at  $40^\circ$  1.86 (Schönfeld, *A.* 93, 26; 95, 10). S. in alcohol at  $5^\circ$  14.78, at  $15^\circ$  9.54, at  $20^\circ$  7.41, at  $25^\circ$  5.62 (Carius, *A.* 94, 140). H.F. (from white amorphous  $\text{S}$ ) [ $\text{H}_2\text{S}$ ] = 4.740; [ $\text{H}_2\text{S}_2\text{Aq}$ ] = 9.200; [ $\text{H}_2\text{S}_2\text{Aq}$ ] = 4.560 (*Th.* 2, 63). Vapour-pressures of condensed  $\text{H}_2\text{S}$  in atmos. (Faraday, *T.* 1845, 1, 55)  $-70^\circ = 1.09$ ,  $-50^\circ = 2.0$ ,  $-40^\circ = 2.86$ ,  $-31^\circ = 3.95$ ,  $-18.9^\circ = 5.96$ ,  $-3.33^\circ = 6.36$ ,  $+8.9^\circ = 13.7$ ,  $11.1^\circ = 14.6$ .

The gas was known in the 16th and 17th centuries; it was first accurately examined by Scheele, who regarded it as a compound of sulphur, phlogiston, and heat.

**Occurrence.**—In gases from volcanoes and fumaroles. In many mineral waters, e.g. the Harrogate water. Sometimes in small quantities in sea-water. It is said to be found in some new wines, probably formed by the acids decomposing sulphides produced by the reduction of sulphates during fermentation.

**Formation.**—1. By the decay of organic matter containing S compounds, or of organic matter free from S in presence of gypsum.—2. By heating various organic bodies, e.g. suet or paraffin (Reinsh, *J. pr.* 1838, 42; Galletly, *C. N.* 24, 162) with  $\text{S}$ .—3. By the dry distillation of S-containing organic material, e.g. gas-coal.—4. By reactions between various acids and metallic sulphides.—5. By the reaction of conc. hot  $\text{H}_2\text{SO}_4$  with  $\text{Zn}$  and some other metals.—6. By the electrolysis of conc.  $\text{H}_2\text{SO}_4$ .—7. By heating  $\text{S}$  with very conc.  $\text{HIAq}$ .—8. The direct union of  $\text{H}$  and  $\text{S}$  occurs when  $\text{H}$  and  $\text{S}$  vapour are passed over pumice at  $c. 400^\circ$  (Corenwinder, *A. Ch.* [3] 34, 77), or when  $\text{H}$  is passed over boiling  $\text{S}$  or is burnt in  $\text{S}$  vapour (Cossa, *B.* 1, 117; Merz a. Veith, *B.* 2, 341; cf. Myers, *B.* 5, 269), or by passing electric sparks through a mixture of  $\text{H}$  and  $\text{S}$  vapour (Chevrier, *C. R.* 69, 136; cf. Boillot, *C. R.* 70, 97; and also Grove, *C. J.* [2] 1, 263).—9. Boiling water is said not to be decomposed by  $\text{S}$  (J. de Girard, *C. R.* 56, 797); Gelis, *C. R.* 56, 1014; Geitner, *A.* 129, 351; Cossa, *B.* 1, 111), but the experiments of Cossa a. Higgins (*C. J.* 35, 249) make it very probable that when  $\text{S}$  is boiled with water small quantities of  $\text{H}_2\text{S}$  are produced. By heating  $\text{H}_2\text{O}$  with  $\text{S}$  to  $200^\circ$  (Geitner, *A.* 129, 351), or by passing steam and  $\text{S}$  vapour through a glowing glass tube (Myers, *J. pr.* 103, 123)  $\text{H}_2\text{S}$  is produced.

**Preparation.**—1. Iron sulphide,  $\text{FeS}$ , in small pieces is placed in a flask connected with a washing apparatus containing water, and dilute  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$ , about 3 to 4 parts water to 1 part conc. acid, is added little by little, with shaking. (The  $\text{FeS}$  may be conveniently prepared by heating three parts  $\text{Fe}$  filings with 2 parts powdered  $\text{S}$ .) If the  $\text{H}_2\text{S}$  is to be collected over water, hot water should be used; if it is necessary to store it in a gasholder a solution of brine should be employed in the gasholder. The gas may be dried by passing through a succession of  $\text{CaCl}_2$  tubes ( $\text{H}_2\text{SO}_4$  must not be used, as it decomposes  $\text{H}_2\text{S}$ ). The  $\text{H}_2\text{S}$  thus prepared usually contains  $\text{H}$  (as the  $\text{FeS}$  usually contains  $\text{Fe}$ ), and frequently hydrides of  $\text{As}$  and  $\text{Sb}$ . Various methods have been suggested to get rid of possible traces of  $\text{AsH}_3$ ; O. von der Pfordten recommends to pass the dried gas through a tube con-

taining commercial 'liver of sulphur' heated to 350°-360°, and then through  $\text{Na}_2\text{CO}_3\text{Aq}$  (B. 17, 3897). Jacobsen (B. 20, 1999) says that every trace of As may be removed by passing the gas through 2 or 3 grams of coarsely-powdered, air-dried I, interspersed with glass-wool placed in a tube at the ordinary temperature.—2. Pure *Stibnite*  $\text{Sb}_2\text{S}_3$  is decomposed by dilute  $\text{HClAq}$ ; the  $\text{H}_2\text{S}$  is nearly pure.—3. Fresenius (Fr. 20, 339) recommends the use of calcium sulphide. It is prepared by strongly heating a mixture of plaster of Paris and charcoal; the sulphide is mixed with one-fourth its weight of plaster of Paris and enough water to make a cream; the whole is poured into shallow paper trays; after setting the block is cut into pieces, which are dried at a gentle heat. By placing the dried pieces in a Kipp's apparatus and adding dilute  $\text{HClAq}$ , a stream of  $\text{H}_2\text{S}$  is obtained which can be readily controlled.—4. According to Divers a. Shimidzu (C. J. 46, 699) an aqueous solution of Mg hydrosulphide is a most convenient source of  $\text{H}_2\text{S}$ , as the pure gas is evolved by heating this solution to c. 60°. The solution is prepared by passing  $\text{H}_2\text{S}$  (made from ordinary FeS) into a large flask about half full of water containing magnesia (preferably freshly calcined) in suspension; not more than about 1 part commercial magnesia should be used to 10 parts water; when the magnesia has all dissolved the solution is placed in a flask with delivery tube and warmed to c. 60° on a water-bath, when a steady evolution of pure  $\text{H}_2\text{S}$  proceeds; by raising the temperature to 90°-100° more  $\text{H}_2\text{S}$  is obtained. The solution of Mg hydrosulphide may be kept unchanged by closing the flask with a cork covered with paraffin. When the solution has been exhausted it is allowed to cool, and then again charged with  $\text{H}_2\text{S}$ , when it is ready for use again.

Many pieces of apparatus have been introduced for the preparation and use of  $\text{H}_2\text{S}$  in laboratories; they are described in *Manuals of Analytical Chemistry*.

**Properties.**— $\text{H}_2\text{S}$  is a colourless gas with a most offensive odour; it is very poisonous; sol. in c.  $\frac{1}{4}$  vol. of  $\text{H}_2\text{O}$ , more sol. in alcohol (v. data at beginning of art.).  $\text{H}_2\text{S}$  is liquefied by pressure and cold. The most convenient method, on the small scale, is to place some H persulphide (not thoroughly dried) (v. p. 727) in a  $\wedge$  shaped tube; the persulphide is gradually decomposed by the moisture into  $\text{H}_2\text{S}$  and S; after a few weeks the other limb of the tube is placed in a freezing mixture, and  $\text{H}_2\text{S}$  distils into, and liquefies in, this limb. Melsens (C. R. 77, 781) allows charcoal to absorb  $\text{H}_2\text{S}$ , places the charcoal in one limb of a  $\wedge$  tube, the other limb being in a freezing mixture, and distills. If  $\text{H}_2\text{S}$  made in the ordinary way is to be liquefied by pressure, care must be taken that the gas is free from H. c. Liquid  $\text{H}_2\text{S}$  is a very mobile, transparent, refractive liquid; S.G. c. 9; boils at -61° at 760 mm. pressure, and solidifies at -85°.  $\text{H}_2\text{S}$  is easily burnt in air to  $\text{H}_2\text{O}$  and  $\text{SO}_2$ ; it is decomposed by-passing through a hot tube at c. 400° (Myers, A. 159, 124), or by passing electric sparks through it.  $\text{H}_2\text{SAq}$  decomposes by exposure to air with separation of S. For an examination of the rate of decomposition of  $\text{H}_2\text{SAq}$  under different conditions v. Baab (M. 12, 10). The solution keeps best in a

corked bottle inverted under water. In the chemical relations  $\text{H}_2\text{S}$  is similar to  $\text{H}_2\text{O}$ , but it is more decidedly acidic;  $\text{H}_2\text{SAq}$  reacts as a monobasic acid.

**Reactions.**—1.  $\text{H}_2\text{S}$  is easily decomposed; when heated to c. 400° it is separated into its elements (Myers, A. 159, 124); it is also decomposed by electric sparks.—2. When burnt in air  $\text{SO}_2$  and  $\text{H}_2\text{O}$  are produced.—3.  $\text{H}_2\text{SAq}$  soon decomposes, with separation of S, by exposure to the air.—4. Moist  $\text{H}_2\text{S}$  warmed in presence of air or oxygen produces  $\text{H}_2\text{SO}_4$ .—5. Most oxidising agents react with  $\text{H}_2\text{SAq}$  to form  $\text{H}_2\text{O}$ , S, and  $\text{SO}_2\text{Aq}$  or  $\text{SO}_3\text{Aq}$ ; thus  $\text{HNO}_3\text{Aq}$  and  $\text{HNO}_2\text{Aq}$  produce  $\text{H}_2\text{O}$ , S, and NO;  $\text{HClO}_4\text{Aq}$  produces  $\text{H}_2\text{O}$ , HCl, and S; alkaline iodates are reduced to iodides.—6. Ferrous salts are reduced to ferrous salts, with separation of S.—7. When  $\text{H}_2\text{S}$  is passed into  $\text{SO}_3\text{Aq}$  until the latter is incompletely decomposed the solution is known as *Wackenroder's solution*; this liquid probably contains S in suspension, a colloidal form of S in solution,  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{S}_2\text{O}_3$ ,  $\text{H}_2\text{S}_4\text{O}_6$ , and a higher thionic acid, probably  $\text{H}_2\text{S}_6\text{O}_{11}$ ; if the passage of  $\text{H}_2\text{S}$  is continued until all chemical change ceases the final products are S and  $\text{H}_2\text{O}$ , thus  $2\text{H}_2\text{S} + \text{SO}_3 = 3\text{S} + 2\text{H}_2\text{O}$  (Debus, C. J. 63, 242; v. THIONIC ACIDS, in vol. iv.).—8.  $\text{H}_2\text{S}$  or  $\text{H}_2\text{SAq}$  is decomposed by chlorine and bromine to  $\text{HX}$  and S;  $\text{H}_2\text{SAq}$  is similarly decomposed by iodine, but if water is not present  $\text{H}_2\text{S}$  does not react with I.—9. Very many metals decompose  $\text{H}_2\text{S}$  when heated with it, forming sulphides and H; several metals, e.g. Ag, Cu, Hg, react at ordinary temperatures. The decomposition of  $\text{H}_2\text{S}$  by hot Sn or Pt has been employed in the analysis of the compound; a specified volume of the gas is thus found to give its own volume of H.—10. Many metallic oxides and salts react with  $\text{H}_2\text{S}$  to form sulphides, and water or acids. The metallic sulphide, if insoluble in, and unacted on by, the acid produced in the reaction, is ppt. when  $\text{H}_2\text{S}$  is passed into a solution of the metallic salt; if the metallic sulphide is decomposed by the acid produced in the reaction, or if it cannot exist in presence of water, no ppt. is formed. These reactions are applied in the systematic qualitative analysis of metallic salts (v. ANALYSIS, vol. i. p. 220).

11.  $\text{H}_2\text{SAq}$  reacts as a weak monobasic acid e.g. with  $\text{KOHAc}$  it forms  $\text{KSHAq}$ . Thomson (Th. 1, 262) gives the following heats of neutralisation:

**Combinations.**—By compressing  $\text{H}_2\text{S}$  in presence of a little water De Forcrand a. Villard obtained a solid hydrate  $\text{H}_2\text{S} \cdot 7\text{H}_2\text{O}$  (C. R. 106, 1402; cf. 106, 849 a. 939); this hydrate is easily decomposed by heat. The formation of the hydrate occurs with a large absorption of  $\text{H}_2\text{S}$  by the water; when formed at 0°, the pressure being about 60 mm. above the ordinary, 1 c.c. water absorbed about 100 c.c.  $\text{H}_2\text{S}$ , whereas the solubility of  $\text{H}_2\text{S}$  in water at 0° and ordinary pressure is only about 4 vols. in 1 vol. water. Wohler (A. 68, 125) obtained ice-like crystals by leading  $\text{H}_2\text{S}$  into alcohol containing water at -18°, the quantity of water being such that by

## HYDROGEN.

ice was formed at the temperature of experiment; these crystals may have been a solid hydrate of  $H_2S$ .

**Detection and estimation.**— $H_2S$  is detected by its smell, by its reaction with a salt of Pb or Ag in solution to give brown-black PbS or black Ag<sub>2</sub>S, and by the production of a deep purple-red colour when brought into contact with an alkaline solution of Na nitroprusside ( $FeCy_2(NO)Na$ ). Finely divided Ag shaken with water containing  $H_2S$  forms Ag<sub>2</sub>S; it does not, however, decompose alkaline sulphides; these reactions may be applied to detect alkaline sulphides in presence of  $H_2S$ ; air must not be present, else salts of S oxyacids may be formed.  $H_2S$  in aqueous solution may be determined by adding a standardised solution of I in KIAl until a permanent blue colour is produced in presence of starch. The solution of  $H_2S$  must be so dilute that not more than .04 p.c.  $H_2S$  is present.

**HYDROGEN PERSULPHIDE** ? $H_2S_2$  or  $H_2S_3$ . When an acid is added to an aqueous solution of an alkaline or alkaline earth persulphide,  $H_2S$  is evolved and the rest of the S is pptd. But if the alkaline persulphide solution is poured into the acid, oily drops sink to the bottom; the oil is a compound of H and S containing relatively more S than  $H_2S$  (Schæk, *Vor der Luft und dem Feuer*, 159; Berzelius, *Lehrbuch*, 2, 218; Thénard, *A. Ch.* 48, 79; Liebig, *A. Z.* 27, 18, 170). Analyses of the oil thus obtained have given discordant results; Ramsay's analyses (*C. J.* (2) 12, 857) showed a composition varying from  $H_2S_2$  to  $H_2S_3$ . According to Sabatier (*C. R.* 100, 1348), if the oil is thoroughly dried, it may be distilled at 60°–85° under a pressure of 40 to 100 mm.; and the liquid thus obtained has the composition  $H_2S_2$ . The analyses of Rebs (*A.* 246, 356) also point to this formula: he decomposed  $Na_2S_3$ ,  $Na_2S_4$ ,  $Na_2S_5$ , and  $Na_2S_6$ , separately with cold HClAq, also different polysulphides of Ca and Ba; in each case he got an oil the composition of which agreed with the formula  $H_2S_2$ . Sabatier thinks that the liquid obtained by him contained S produced by the decomposition of part of the persulphide; he is in favour of the formula  $H_2S_2$  for the persulphide.

Hofmann (*B.* 1, 81) by the reaction between yellow  $NH_4$  sulphide and strychnine obtained a well-crystallised compound  $C_{11}H_{12}N_4O_2.H_2S_2$ , which was decomposed by acids with separation of H persulphide; this formula was confirmed by Ramsay (*C. J.* (2) 12, 857). Schmidt allowed  $H_2S_2$  to react with strychnine in presence of air, and obtained crystals of  $3C_{11}H_{12}N_4O_2.2H_2S_2$ ; with brucine he got the compounds  $C_{15}H_{18}N_4O_2.H_2S_2.2H_2O$  and  $C_{15}H_{18}N_4O_2.2H_2S_2$ ; those compounds were decomposed by acids giving a yellow oil which had the properties of H persulphide.

The composition of H persulphide cannot be regarded as settled; possibly more than one compound  $H_2S_x$  exists.

**Preparation of H persulphide.**—An aqueous solution of an alkaline polysulphide is slowly poured into excess of a solution of about equal parts of conc. hydrochloric acid and water; the liquid is placed in a filter in the neck of which oily drops collect, this oil is run off and dried over  $CaCl_2$ . To prepare the alkaline poly-

sulphide, conc. KOHAq may be boiled with S; or 2 parts  $K_2CO_3$  may be fused with 1 part S, the mass dissolved in water, boiled with excess of S, and allowed to clear; or 1 part CaO may be made into a thin cream with water and boiled with 2 parts S. As solution of polysulphides prepared as described may contain thiosulphates, Berthelot (*A. Ch.* [3] 49, 450) recommends to saturate KQHAq with  $H_2S$  out of contact with air, to add an equal volume of the same KOHAq, and to boil with S; or  $Na_2SO_3$  or  $CaSO_3$  may be strongly heated with powdered charcoal, the mass treated with water, and boiled with S. Sabatier (*C. R.* 100, 1346) thoroughly dries the oil, places it in a small flask with short neck connected with a bulb-tube surrounded by ice and having a pump attached; when the pressure is reduced to 40–100 mm. he heats the flask to 60°–80° in a water-bath.

**Properties.**—A yellow, mobile, oily liquid; S.G. 1.734 (Ramsay), 1.71 at 15° (Rebs). Odour is very irritating; taste bitter-sweet; the liquid raises blisters on the skin; it is soluble in  $C_2H_5$ ,  $CHCl_3$ , and  $CS_2$ ; decomposed by alkalis, alcohols, and slowly by ether; also by the action of light; slowly decomposed by  $KMnO_4$ , Ag, Br, I,  $HNO_3$ , Aq (Sabatier, *C. R.* 100, 1585). Hydrogen persulphide is more stable when the liquid contains some S or  $H_2S$  (Sabatier). When quite dry, the liquid may be preserved unchanged in a sealed tube (Bunsen, *P.* 46, 103); if the liquid is not quite dry, it slowly decomposes into crystals of S and liquid  $H_2S$ , if this change proceeds the tube may be broken by the pressure of the  $H_2S$ . Hydrogen persulphide is readily inflammable.

**Reactions.**—Hydrogen persulphide resembles  $H_2O_2$  in its reactions; it is decomposed to  $H_2S$  and S by those substances which change  $H_2O_2$  into  $H_2O$  and O, e.g. Pt, Au, Ag, charcoal powder, &c.; it acts as a reducing agent, e.g. it decolourises indigo. Water decomposes it to  $H_2S$  and S, slowly at ordinary, quickly at higher temperatures. Ammonia causes a pptn. of S; ether acts slowly producing nacreous S; according to Sabatier (l.c.), hydrochloric acid, dry air, and dry hydrogen have no action.

Hydrogen telluride  $H_2Te$  (Telluretted hydrogen. Tellurhydric acid. Hydrotelluric acid. Tellurium hydride). Mol. w. 127. This compound, discovered by Davy (*G. A.* 37, 1810) resembles  $H_2S$  and  $H_2Se$ . It is formed by direct union of its elements, by heating Te in a stream of H (Löwe, *W. A. B.* 10, 727; Becker *A.* 180, 257); also by decomposing ZnTe by dilute HClAq. Berthelot & Fabre (*A. Ch.* [6] 14, 103) recommend the use of MgTe, prepared by action of excess of Te vapour on heated  $M_2$  in an atmosphere of pure H; they decompose the MgTe in an atmosphere of pure N by very dilute HClAq.  $TeH_2$  is a colourless gas, with disagreeable smell, which is different from that of  $H_2Se$  or  $H_2S$ ; when inhaled, the effects are not so irritating as in the case of  $H_2Se$  (q.v.) (B. a. F., l.c.).  $TeH_2$  is very unstable; it soon decomposes over dry Hg, even in the dark; in presence of moist air, decomposition is instantaneous (B. a. F., l.c.).  $TeH_2$  is decomposed by heat; according to Ditté (*C. R.* 74, 980) this decomposition is less complete at higher than at lower temperatures; the behaviour is exactly similar to that of  $SeH_2$  (q.v. p. 725).  $TeH_2$

readily combustible, and is fairly soluble in water, the solution is very quickly decomposed if exposed to air. Pure  $\text{TeH}_2$  is rapidly and completely absorbed by solutions of alkalis, with production of alkali tellurides, if a trace of O is present the solution becomes violet or purple, and if much O is present Te is pptd. (B. a. F., &c.).  $\text{TeH}_2$  passed into solutions of metallic salts ppt. metallic tellurides. M. M. P. M.

**HYDRO-HOMO-FERULIC ACID** *v. m-Methyl derivative of (4:3:1)-Di-oxy-phenyl-iso-butyric acid.*

**HYDROIODOANGELIC ACID** *v. Iodo-VALERIC ACID.*

**HYDROIODOCINNAMIC ACID** *v. Iodo-PHENYL-PROPIONIC ACID.*

(a)-**HYDROJUGLONE**  $\text{C}_{10}\text{H}_6\text{O}_2$ . *Oxy-(a)-hydro-naphthoquinone!* [170°]. S. (at 25°) = 5. Occurs, together with about  $\frac{1}{2}$  as much (β)-hydrojuglone, in the leaves and unripe green shells of the walnut. Formed by reduction of juglone (Mylus, B. 17, 2411; 18, 475, 2567). Colourless plates or needles. V. a. sol. alcohol, ether, and acetic acid, nearly insol. benzene and petroleum-ether, insol. chloroform. It dissolves in aqueous  $\text{NaOH}$  with a yellow colour, which almost instantly becomes violet on exposure to air from formation of juglone. It is odourless, but possesses a burning taste, and is poisonous;  $\frac{1}{2}$  g. killed a rabbit in 2 hours. By treatment with acid anhydrides it is converted into the alkyl derivatives of (β)-hydrojuglone. On heating (a)-hydrojuglone above its melting-point, it is converted into the (β)-isomeride. On the other hand the inverse change takes place if (β)-hydrojuglone is boiled with dilute HCl for a long time. Potash-fusion gives *oxy-benzoic acid*, together with phenol, salicylic acid, and pyrocatechin. Oxidising agents very readily convert it into juglone. On distillation with zinc dust it gives *naphthalene*.

*Tri-acetyl derivative*  $\text{C}_{18}\text{H}_6(\text{OAc})_3$ , [24°].

(β)-**Hydrojuglone**  $\text{C}_{10}\text{H}_6\text{O}_2$ . *Tri-oxy-naphthalene!* [97°]. S. (at 25°) = 11. Occurs, together with about 5 times as much (a)-hydrojuglone, in the unripe shells of the walnut. Silvery six-sided tables or flat needles. V. sol. chloroform and benzene, fl. sol. cold alcohol and ether, volatile with steam. Aromatic smell and burning taste. Formed by heating (a)-hydrojuglone above its melting-point. Converted into the (a)-hydrojuglone by long boiling with dilute HCl. Dissolves in alkalis with a yellow colour, which becomes red on exposure to the air.  $\text{FeCl}_3$  gives a blood-red colouration. It is not oxidised to juglone, except under conditions which allow of the previous conversion into (a)-hydrojuglone. Its alkyl derivatives are formed by the action of anhydrides upon either (a)- or (β)-hydrojuglone.

*Tri-acetyl derivative*  $\text{C}_{18}\text{H}_6(\text{OAc})_3$ ; [180°]; colourless prisms (from alcohol).

*Tri-benzoyl derivative*  $\text{C}_{22}\text{H}_{10}(\text{OBz})_3$ ; [150°]; colourless needles, al. sol. alcohol and acetic acid, insol. water (Mylus, B. 18, 2567).

**HYDROLUTIDINE** *v. Di-hydride of DI-METHYL-PYRIDINE.*

**HYDROMUCONIC ACID** *v. MUCONIC ACID.*

**HYDROMELLITIC ACID** *v. Hexahydride of MELLITIC ACID.*

**HYDRO-METHYL-KETOLE** *v. METHYL-MUCOLE dihydride.*

**HYDRO-METHYL-PYRIDINES** *v. Hydrides of METHYL-PYRIDINES.*

**DI-HYDRO-TRI-METHYL-PYRIDINE DI-CARBOXYLIC ETHER** *v. Di-hydride of TRI-METHYL-PYRIDINE DI-CARBOXYLIC ETHER.*

**HYDRO-METHYL-PYRROLE** *v. Hydride of METHYL-PYRROLE.*

**HYDRO-METHYL-QUINALDINES** *v. Hydrides of DI-METHYL-QUINALDINES.*

**HYDRO-MUCONIC ACID**  $\text{C}_4\text{H}_4\text{O}_4$ , &c. ( $\text{CO}_2\text{H}$ ).  $\text{CH}_2\text{CH}(\text{OH})\text{CH}_2(\text{CO}_2\text{H})$ . [195°]. S. -9 at 16°. Formed by partial reduction of diacetylene-di-carboxylic acid with sodium-amalgam. Or further reduction it gives adipic acid (Baeyer B. 18, 680). Formed also by treating dichloro muconic acid  $\text{C}_4\text{H}_2\text{Cl}_2\text{O}_4$  with sodium-amalgam (Bode, A. 132, 98). Colourless prisms; v. sl. sol. cold water, v. sol. hot water and alcohol, m. sol. ether. Reduced by sodium-amalgam to adipic acid (Limpricht, A. 165, 263). By treatment with bromine it may be converted into bromo-hydromuconic acid [183°], di-, tri-, and tetra-, bromo-adipic, and iso-di-bromo-adipic acids. —  $\text{ZnA}^+$ . —  $\text{AgA}^+$ .

*Anhydride*  $\text{C}_4\text{H}_2\text{O}_3$ . Trimetric crystals;  $a:b:c = 206:14:382$  (Fock, Z. K. 7, 48).

**HEXA-HYDRO-NAPHTHALENE** *v. NAPHTHALENE HEXAHYDRIDE.*

**TETRA-HYDRO-NAPHTHALENE DI-CARBOXYLIC ACID** *v. Tetrahydride of NAPHTHALENE DI-CARBOXYLIC ACID.*

**DIHYDRO-NAPHTHOIC ACID** *v. so-called v. METHYL-INDONAPHTHENE-CARBOXYLIC ACID.*

(a)-**HYDRO-NAPHTHOQUINONE**  $\text{C}_{10}\text{H}_6\text{O}_2$ , *i.e.*  $\text{C}_{10}\text{H}_6(\text{OH})_2$  [173°] (P.); [176°] (G.).

Formed by the action of fuming  $\text{HNO}_3$  on (a)-naphthoquinone (Groves, A. 167, 359); or, better, from (a)-naphthoquinone, tin, and  $\text{HClAq}$  (Plimpton, C. J. 37, 636). A small quantity may be obtained by heating (a)-naphthoquinone with aqueous  $\text{SO}_3$  at 150° (Plimpton). White needles; m. sol. boiling water, v. sol. boiling alcohol, ether, and  $\text{HOAc}$ , al. sol. hot benzene, almost insol.  $\text{CS}$ , and ligroin. Oxidising agents convert it into (a)-naphthoquinone; with a solution of (a)-naphthoquinone it forms dark-purple crystals of the quinhydrone  $\text{C}_{20}\text{H}_{12}\text{O}_4$ .

*Di-acetyl derivative*  $\text{C}_{18}\text{H}_6(\text{OAc})_2$ , [a. 130°]. Easily soluble tables (from alcohol) (Korn, B. 17, 3025).

(β)-**Hydro-naphthoquinone**  $\text{C}_{10}\text{H}_6(\text{OH})_2$  [1:2]. [c. 60°]. Formed by treating (β)-naphthoquinone with cold conc.  $\text{SO}_3\text{Aq}$  (Liebermann a. P. Jacobson, A. 211, 58). Silvery plates. It dissolves in aqueous alkalis forming yellow solutions which turn deep green in the air. Violently inflames the skin.

*Di-acetyl derivative*  $\text{C}_{18}\text{H}_6(\text{OAc})_2$ , [c. 108°]. Very soluble plates (from  $\text{HOAc}$ ) (Korn, B. 17, 3025).

**Ischydrone-naphthoquinone**  $\text{C}_{10}\text{H}_6\text{O}_2$ . Formed by the action of water (80 pts.) on the compound  $\text{C}_{10}\text{H}_4(\text{HOCl})_2$  (so-called di-chloro-naphthylene glycol) at 150° (Grimaux, B. [2] 19, 897). Small needles; sol. water and ether, insol.  $\text{CHCl}_3$  and benzene. Its alkaline solutions turn red in the air. It reduces ammoniacal  $\text{AgNO}_3$ .  $\text{FeCl}_3$  gives, in its aqueous solution, a brown pp. sol. alkalis.

**HYDRO-O-OXY-BENZ-AMIDE** v. TRI-OXY-HYDROBENZAMIDE.

**HYDRO-OXY-CAMPHORONIC ACID** v. CAMPHOR.

**HYDRO-OXY-METHYL-QUINOLINE** v. *Hydride of Oxy-methyl-quinoline*.

**DI-HYDRO-OXY-QUINOLINE** v. *Hydro-carbonyl under AMIDO-PHENYL-PROPIONIC ACID*; v. also *Hydride of Oxy-quinoline*.

**HYDRO-PHENOL-PHTHALIDIN CHLORIDE** v. DI-CHLORO-PHENYL-ANTHRANOL DIHYDRIDE.

**HYDRO-PHENYL-ACRIDINE** v. PHENYL-ACRIDINE *hydride*.

**HYDRO-PHENYL-CROTONIC ACID** v. PHENYL-BUTYRIC ACID.

**TETRA-HYDRO-PHENYL-QUINOLINE** v. *Tetra-hydride of Phenyl-quinoline*.

**HYDROPHOBON** v. HYDROXYL-QUINONE.

**HYDROPHTHALIC ACIDS** v. *Hydrides of PHTHALIC ACID*.

**HYDRO-PICOLINE** v. *Hydride of METHYL-PYRIDINE*.

**HEXA-HYDRO-PICOLINIC ACID** v. *Hexa-hydride of PYRIDINE CARBOXYLIC ACID*.

**HYDRO-PIPERIC ACIDS**  $C_8H_{11}O_2$  {a} [78°].

(*a*) [181°]. By reduction of piperic acid by sodium-amalgam two hydro-piperic acids are got. They may be separated by crystallisation from alcohol, when the (*β*)-acid separates first. The (*α*)-acid is the chief product (Foster, A. 124, 117; Fittig a. Mielok, A. 162, 56). The (*β*)-acid forms thin needles (from alcohol). Its ammonium salt is more soluble than that of the (*α*)-acid. The (*β*)-acid is only formed when the liquid becomes very alkaline, if the alkali be constantly neutralised during the reduction only (*α*)-acid is got. The (*α*)-acid may be converted into the (*β*)-acid by heating with (10 pts.) of dilute (10 p.c.) NaOH 9 hours at 100° (Lorenz, B. 14, 785; Fittig a. Burri, A. 216, 171; 227, 81; Weinstein, A. 227, 32). Br in CS<sub>2</sub> converts the (*α*)-acid into its dibromide, di-bromo-piperhyronic acid  $C_8H_8Br_2O_2$  [187°-140°], while the (*β*)-acid gives a product of substitution, bromo-hydro-piperic acid [171°]. The (*β*)-acid is reduced by sodium amalgam in neutral solution to piper-hydronic acid, while the (*α*)-acid is not reduced thereby.

(*α*)-Hydropiperic acid

Thin needles (from hot water); sl. sol. hot water, v. e. sol. alcohol and ether. Oxidised by CrO<sub>3</sub> to acetic acid. KMnO<sub>4</sub> gives piperonal, oxalic acid, and di-oxy-piperhyronic acid  $CH_2O_2C_6H_8O_2$  (Riegel, B. 20, 415). Not attacked by AcCl at 100°. Potash-fusion gives protocatechuic acid and HOAc.

**Salts.**—NH<sub>4</sub>A': small laminae.—KHA': amorphous, formed by adding K<sub>2</sub>CO<sub>3</sub> to an alcoholic solution of the acid. Decomposed by water.

—AgA': crystalline pp.

(*β*)-Hydro-piperic acid

Got from its (*α*)-isomeride by heating this acid (1 pt.) with NaOH (1 pt.) and water (9 pts.) at 100° for some days. The acid is separated from undecomposed (*α*)-isomeride by crystallisation from alcohol (90 p.c.). Thin needles (from alcohol); less soluble than its isomeride in the same solvent. Bromine forms a substitution,

not an addition, product. KMnO<sub>4</sub> oxidises it to di-oxy-piperhyronic acid  $CH_2O_2C_6H_8O_2$ , and methyl-anhydro-cafeic acid  $CH_3O_2C_6H_8O_2$ .

**HYDROPYRENEQUINONE** v. PYRENE.

**DIHYDROPYRIDINE** v. PYRIDINE DIHYDRIDE.

**HYDRO-PYRO-CINCHONIC ACID** v. DI-METHYL-SUCCINIC ACID.

**HYDROPYROMELLITIC ACID** v. PYRO-MELLITIC ACID.

**DIHYDROPYRROLE** v. PYRROLE DIHYDRIDE.

**TETRA-HYDRO-QUINALDINE** v. (Py. 3)-METHYL-QUINOLINE TETRAHYDRIDE.

**HYDROQUINANISOL** v. *Methyl ether of OXY-QUINOLINE-TETRA-HYDRIDE*.

**HYDROQUINICINE** v. CINCHONA BASES.

**HYDROQUINIDINE** v. CINCHONA BASES.

**HYDROQUININE** v. CINCHONA BASES.

**HYDROQUINOLINE** v. QUINOLINE HYDRIDE.

**TETRA-HYDRO-QUINOLINE HYDRAZINE**

v. AMIDO-TETRA-HYDRO-QUINOLINE.

**HYDROQUINONE**  $C_6H_4O_2$ , i.e.  $C_6H_4(OH)_2$  [14].

*p*-Di-oxy-benzene. Quinol. Pyrogenetic acid. Mol. w. 110. [163°] (Hlasiwetz a. Habermann, B. 8, 684). S.G. 1.326 (Schröder, B. 12, 563). H.F. (from diamond) 86,100 (Berthelot a. Louguine, A. Ch. [6] 13, 337; C. R. 104, 1576); 100,880 (Schumann, J. pr. [2] 33, 471). S. 6-21 at 15°; 10-44 at 28-5°.

**Formation.**—1. By the reduction of quinone, and by the dry distillation of quinic acid (Wöhler, A. 51, 152).—2. From arbutin by boiling with dilute H<sub>2</sub>SO<sub>4</sub>, or by the action of emulsin (Kawaler, A. 84, 258; Strecker, A. 107, 229).—3. By boiling *p*-d zo-phenol sulphate with dilute (12 p.c.) H<sub>2</sub>SO<sub>4</sub> and extracting the cooled product with ether. The yield amounts to 46 p.c. (Wesselsky a. Scher, B. 9, 1159). In like manner hydroquinone may be obtained by the action of water at 140° on  $[4:1]C_6H_4(OMe).N.N.SO_3H$ , derived from the methyl ether of *p*-nitro-phenol (H. Salkowski, B. 7, 1010).—4. By gently heating a dilute solution of nitroso-phenol in NaOH, with hydroxylamine hydrochloride, nitrogen being given off (Hepp, B. 10, 1654).—5. From bromo-salicylic acid  $[4:1:2]C_6H_3Br(OH)(CO_2H)$  by fusion with NaOH, and heating the resulting di-oxy-benzoic acid [197°] in a bath of H<sub>2</sub>SO<sub>4</sub> at 215°, when pure hydroquinone sublimes (Rakowski a. Leppert, B. 8, 788; cf. Demole, B. 7, 1441; Hlasiwetz, A. 175, 67).—6. By passing a current of air for 3 hours through an alkaline solution of succinyl-o-succinic ether, and heating the resulting di-oxy-terephthalic acid with KOH (Herrmann, B. 10, 167).—7. A product of the distillation of succinates (Von Richter, J. pr. [2] 20, 207).—8. By passing a rapidly alternately electric discharge through a solution of phenol (q. v.).—9. From *p*-iodo-phenol by potash-fusion (Körner, Z. 1866, 562, 731).—10. Occurs in the urine of dogs that have taken benzene (Baumann, H. 6 190), phenol (Baumann a. Preusse, B. 12, 706) or arbutin (Mering, Ar. Physiol. 62, 276).

**Preparation.**—Aniline (1 pt.) is dissolved in H<sub>2</sub>SO<sub>4</sub> (8 pts.) diluted with water (30 pts.), and to this solution, after cooling, powdered K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (3½ pts.) is gradually added, too great a rise of temperature being avoided. The thick pulp mass of aniline-black produced at first changes after a time to a dirty-brown solution, which

**Reactions.**—1. Oxidised to quinone by  $\text{FeCl}_3$ , chlorine, dilute  $\text{H}_2\text{O}_2$ , and chromic acid.—2. By passing through a red-hot tube it is split up into quinone and hydrogen (Hesse, A. 114, 2297).—3. Hydroxylamine in acetic solution gives the di-oxim of quinone.—4. Strong nitric acid decomposes hydroquinone in the cold, forming oxalic acid and  $\text{HOY}$  (Nietzki, A. 215, 138).—5. Nitrous acid gas passed into an ethereal solution of hydroquinone at  $0^\circ$  forms small golden needles of di-nitro-*o*-xy-quinone (Nietzki, B. 10, 2147).—6. Not affected by potash-fusion (Wils, A. 189, 91). Soda-fusion converts it into (1,24)-di-*o*-xy-benzene, (6,8)-*o*-xy-diphenyl, and tetra-*o*-xy-diphenyl  $\text{C}_{12}\text{H}_8\text{O}_4$  (Barth, A. Schreiner, A. 6, 176; G. 589).—7. When heated with  $\text{Cl}_2$  it appears to form first  $\text{C}_6\text{H}_3(\text{OH})(\text{OCl})_2$  and then  $\text{C}_6\text{H}_3(\text{OCl})_4$  (Scheidt, A. 218, 207).—8.  $\text{H}_2\text{S}$  passed into a cold saturated solution of hydroquinone forms colourless rhombohedra  $\text{C}_6\text{H}_4(\text{O})_2\text{H}_2\text{S}$  decomposed by boiling water into components (Wöhler, A. 69, 297).  $\text{H}_2\text{S}$  passed into a solution of hydroquinone saturated at  $40^\circ$  forms long prisms of  $\text{C}_6\text{H}_4(\text{O})_2\text{H}_2\text{S}$ —9.  $\text{H}_2\text{S}$  passed into a cold saturated solution of hydroquinone forms yellow rhombohedra  $\text{C}_6\text{H}_4(\text{O})_2\text{H}_2\text{SO}_3$  which gradually decompose (Glemm, A. 110, 857; Hesse, A. 114, 800).—10. *Aldehyde* in presence of dilute  $\text{HCl}$  forms a resin on heating (Michael & Ryder, Am. J. 1881).—11. With acetone it forms an unstable compound  $\text{C}_6\text{H}_4(\text{O})_2\text{C}_3\text{H}_7\text{O}$ , which forms triclinic crystals, decomposed into its components by solution in alcohol, acetone, or hot water, and even by exposure to air (Haber-

mann, M. 5, 829).—12. HOy forms needles (C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>), HOy decomposed by heat or by water into its components (Mylus, B. 19, 1008).—13. Aniline when boiled with hydroquinone forms C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>(NHPh), which crystallises in large plates [80°], sol. alcohol and hot water. Its solution on exposure to the air is oxidised to quinone dianilide. By boiling with benzene it is resolved into hydroquinone and aniline (Hebebrand, B. 15, 1978). Hydroquinone (1 mol.) heated with aniline (4 mola.) and CaCl<sub>2</sub> at 260° gives C<sub>6</sub>H<sub>5</sub>(OH)(NPh) [70°] (Calm, B. 16, 2786). In like manner *o*-toluidine and CaCl<sub>2</sub> at 246° give C<sub>6</sub>H<sub>5</sub>(OH)(NHCH<sub>3</sub>) [90°].—14. *p*-Toluidine forms C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>(C<sub>6</sub>H<sub>4</sub>NH<sub>3</sub>) [98°] (Hebebrand, B. 15, 1974).—15. By heating with phenyl cyanate at 100° there is formed C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>(C.CO.NPh), which crystallises from alcohol in prisms (c. 207°). It is insol. benzene. At its melting-point it begins to decompose into phenyl cyanate and hydroquinone (Snape, C. J. 47, 772).—16. Chloroformic ether ClCO<sub>2</sub>Et acting on sodium hydroquinone forms *p*-phenylene di-carbonic ether C<sub>6</sub>H<sub>4</sub>(O.CO<sub>2</sub>Et)<sub>2</sub>. This crystallises from alcohol in long needles, [100°], (810°), and appears to be split up by heat into CO<sub>2</sub> and mono-ethyl hydroquinone (245°–250°) (Bender, B. 13, 496; Wallach, A. 226, 85).—17. Chloroformic acid gives C<sub>6</sub>H<sub>4</sub>(O.CONF<sub>3</sub>)<sub>2</sub>, which crystallises from alcohol in small needles [236°].—18. Heated with ZnCl<sub>2</sub> and glacial acetic acid it gives di-ox-phenyl methyl ketone (Nencki and W. Schmid, J. pr. [2] 23, 546).—19. Di-chloro-di-ethyl oxide in warm EtOAc forms C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.OH(C<sub>6</sub>H<sub>5</sub>(OH))<sub>2</sub>, an amorphous substance, sol. alcohol, acetone, HOAc, and alkalis, and forming a hexa-acetyl derivative. FeCl<sub>3</sub> converts it into a green colouring matter C<sub>6</sub>H<sub>4</sub>O<sub>2</sub>, whence bromine forms C<sub>6</sub>H<sub>3</sub>Br<sub>3</sub>O<sub>2</sub>. When an excess of di-chloro-di-ethyl oxide acts on a solution of hydroquinone in EtOAc there is formed a resin and a soluble compound C<sub>6</sub>H<sub>4</sub>O<sub>2</sub>Cl<sub>2</sub> (Wislicenus a. Siegtfried, A. 243, 171).—20. Formic acid forms a compound (C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>)CH<sub>2</sub>O<sub>2</sub>, which crystallises in needles, and melts at 60°, giving off formic acid. It is also decomposed into its constituents by solution in water (Mylus, B. 19, 1008). When hydroquinone (1 pt.) is heated with crystallised formic acid (2 pts.) for 4 hours at 250° there is formed a crystalline mixture of (C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>)CH<sub>2</sub>O<sub>2</sub> and an anhydride thereof. The anhydride (C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>O<sub>2</sub> crystallises in colourless glassy needles, split up by water, alcohol, or ether, into CO<sub>2</sub>, formic acid, and hydroquinone (Mylus, B. 19, 999).—21. KHCO<sub>3</sub> (4 pts.) heated in a digester with hydroquinone (1 pt.) and water (4 pts.) forms di-ox-benzoic acid, the yield being about 20 p.c. (Sephert a. Sarley, M. 2, 449).—22. *Mr*ic acid and H<sub>2</sub>SO<sub>4</sub> form ox-  
CHCH=CO—CO—CO  
coumarin  
C(OH)=CH.C(OH)=CH  
mann a. Welsh, B. 17, 1646. With KOH and K<sub>2</sub>S<sub>2</sub>O<sub>8</sub> it forms potassium ox-phenyl sulphate (C<sub>6</sub>H<sub>5</sub>O)<sub>2</sub>SO<sub>3</sub>K crystallising in trimetric tables (Bachmann, B. 11, 1918).

*Acetyl dehydrostearate*  $C_{27}H_{44}(OAc)_2$  (1917).  
Formed, slowly, by the action of  $AcCl$  on hydroquinone in the cold (Nietzki, B. 11, 470). Formed also by heating quinone with  $NaOAc$  and  $Ac_2O$  or glacial  $HOAc$  at  $100^\circ$  (Hesse, A. 290, 365), or

y heating quinone with  $\text{Ac}_2\text{O}$  at  $260^\circ$  (Sarauw, 209, 128). Long needles (from alcohol), lates, or tables. V. sol. benzene, chloroform, and ether, m. sol. alcohol and hot water. May be sublimed. Split up by long boiling with water into  $\text{HOAc}$  and hydroquinone. If it be treated with  $\text{PCl}_5$  and the product distilled with steam, white needles of  $\text{C}_6\text{H}_4(\text{O})_2$  [66°] are got (Michael, *Am.* 9, 211). This body, which may be  $\text{C}_6\text{H}_4(\text{OH})(\text{OCCl}_2\text{CCl}_2)$ , is sl. sol. hot water, sol. in ether, benzene, and alcohol. It dissolves in  $\text{KOH}$  and is reprecipitated by acids. With  $\text{AcCl}$  it gives an acetyl derivative.

**Propionyl derivative**  $\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5\text{O})_2$ . [13°]. Large plates (from alcohol); v. sol. chloroform and ether, sl. sol. hot water (Hesse, 200, 246). Gives a nitro-derivative [86°].

**Benzoyl derivative**  $\text{C}_6\text{H}_4(\text{O}_2\text{CPh})_2$ . [199°]. Silky needles (from benzene); v. sl. sol. boiling alcohol (Dobner, *A.* 210, 263).

**Methyl ether**  $\text{C}_6\text{H}_4(\text{OMe})_2$ . [58°]. [42°]. Formed, together with hydroquinone, by boiling arbutin with dilute  $\text{H}_2\text{SO}_4$ ; formed also, together with the di-methyl ether, by heating hydroquinone with  $\text{KOH}$  and  $\text{KMnO}_4$  at  $70^\circ$  (Hlasgutzsch & Habermann, *A.* 177, 838). Prepared by heating hydroquinone (2 pts.) with  $\text{MeI}$  (1 pt.),  $\text{MeI}$  (3 pts.), and some  $\text{MeOH}$  at  $10^\circ$  (Hesse, *A.* 200, 254). Flat white needles (Tiemann, *B.* 14, 1989) or trimetric plates. Not volatile with steam (difference from the di-nethyl ether). V. mol. cold benzene (difference from hydroquinone). Sol. boiling water.  $\text{FeCl}_3$  converts it into quinhydrone. It reduces hot ammoniacal  $\text{AgNO}_3$ . Fuming  $\text{HNO}_3$  dissolved in ether forms a mono- and a di-nitro-derivative, melting at  $88^\circ$  and  $102^\circ$  respectively (Weselsky & Benedikt, *Sitzb. W.* [2] 84, 258).— $\text{C}_6\text{H}_4(\text{OMe})(\text{OK})$ : crystalline powder; insol. ether (Michael, *Am.* 5, 177).

**Di-methyl ether**  $\text{C}_6\text{H}_4(\text{OMe})_2$ . [56°]. H.F.p. 81,924 ( $\text{C}_{10}\text{H}_{12}\text{O}_2$ —94,000;  $\text{H}_2\text{O}$ —69,000) (Stohmann, *J. pr.* [2] 35, 28). Formed by boiling hydroquinone (78 g.) under 960 mm. pressure, with  $\text{KOH}$  (93 g.), and  $\text{MeI}$  (234 g.) dissolved in  $\text{MeOH}$  (Mühlhanser, *A.* 207, 252). Large plates. Reduces hot ammoniacal  $\text{AgNO}_3$ .  $\text{FeCl}_3$  forms quinhydrone.

**Mono-ethyl ether**  $\text{C}_6\text{H}_4(\text{OEt})(\text{OH})$ . [66°]. [247°]. From the ethyl derivative of the sulphate of diazo-phenol by boiling with water and extracting with ether (Hantzsch, *J. pr.* [2] 22, 464). Also from hydroquinone,  $\text{KOH}$ , and  $\text{MeI}$  (Wichelhaus, *B.* 12, 1601). Thin plates (from water). Sl. sol. cold water; v. sol. hot water, alcohol, and ether. Slightly volatile with steam. Boiled with dilute hydric iodide and a little alcohol it forms hydroquinone. Conc.  $\text{HI}$  at high temperatures carbonizes it. Although hydroquinone forms no aldehyde by Tiemann & Reimer's method, yet ethyl-hydroquinone (14 g.) with  $\text{NaOH}$  (20 g.) and water (36 g.) at  $60^\circ$  is converted into a di-oxo-benzoic aldehyde by running in chloroform (15 g.).

**Di-ethyl ether**  $\text{C}_6\text{H}_4(\text{OEt})_2$ . [124°]. From hydroquinone,  $\text{NaOH}$ , and  $\text{EtI}$  (Nietzki, *A.* 215, 148). Plates; volatile with steam. V. sol. alcohol, ether, chloroform, and benzene.

**Methyl ethyl ether**  $\text{C}_6\text{H}_4(\text{OMe})(\text{OEt})$ . [59°]. Prepared by heating the mono-methyl ether with  $\text{K}_2\text{SO}_4$  and  $\text{KOH}$ , and distilling the

product (Fiala, *M.* 5, 292). Colourless crystalline mass, smelling like oil of fennel. Insol. water, sol. benzene and ether.

**Methyl propyl ether**  $\text{C}_6\text{H}_4(\text{OMe})(\text{OPr})$ . [24°]. From the mono-methyl ether,  $\text{KOH}$ , and potassium propyl sulphate. Purified by frequent distillation with steam (F.). Leaflets; insol. water, sol. benzene, ether, and alcohol.

**Ethyl propyl ether**  $\text{C}_6\text{H}_4(\text{OEt})(\text{OPr})$ . [36°]. Pearly plates (from  $\text{HOAc}$ ).

**Methyl isobutyl ether**  $\text{C}_6\text{H}_4(\text{OMe})(\text{OCH}_2\text{Pr})$ . (227°–280°). From  $\text{C}_6\text{H}_4(\text{OH})(\text{OMe})$ ,  $\text{KOH}$ , and potassium isobutyl sulphate. Purified by fractional distillation. Heavy oil, with aromatic odour; sol. benzene, ether, and alcohol (F.).

**Ethyl isobutyl ether**  $\text{C}_6\text{H}_4(\text{OEt})(\text{OCH}_2\text{Pr})$ . [39°]. Lamine (Fiala, *M.* 6, 910).

**Propyl isobutyl ether**  $\text{C}_6\text{H}_4(\text{OPr})(\text{OCH}_2\text{Pr})$ . (245°). Oil.

**Di-isobutyl ether**  $\text{C}_6\text{H}_4(\text{OCH}_2\text{Pr})_2$ . (262°). Formed by heating hydroquinone with  $\text{KSO}_4$ ,  $\text{CH}_3\text{Pr}$  and  $\text{KOH}$  in sealed tubes at  $150^\circ$ , being isolated by distilling the product with steam (Schubert, *M.* 3, 680). Leaflets; insol. water, sol. alcohol and ether. Chlorine forms a di- and a tetra-chloro-derivative, together with tetra-chloro-quinone. Bromine forms a di-bromo-derivative as well as tetra-bromo-quinone. A mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  forms a tetra-nitro-derivative. All these derivatives are crystalline, insol. water, and sol. alcohol and ether.

**Methyl isoamyl ether**  $\text{C}_6\text{H}_4(\text{OMe})(\text{OCH}_2\text{CH}_2\text{Pr})$ . (234°–237°). Oil (Fiala, *M.* 6, 910).

**Ethyl isoamyl ether**  $\text{C}_6\text{H}_4(\text{OEt})(\text{OCH}_2\text{CH}_2\text{Pr})$ . (252°). Oil.

**Benzyl derivative**  $\text{C}_6\text{H}_4(\text{CH}_2\text{C}_6\text{H}_5\text{O})_2$ . [123°–5°]. Formed from benzyl-arbutin (v. Arbutin) by boiling dilute  $\text{H}_2\text{SO}_4$  (Schiff & Pellizzari, *A.* 221, 369). Formed also from hydroquinone,  $\text{KOH}$ , alcohol, and benzyl bromide. Silvery scales (from water). V. sl. sol. cold water; v. sol. alcohol, ether, and benzene. Sol.  $\text{KOH}$  aq.  $\text{HNO}_3$  forms a di-nitro-derivative [137°].

**Di-benzyl derivative**  $\text{C}_{22}\text{H}_{20}\text{O}_2$ , i.e.  $\text{C}_6\text{H}_4(\text{OCH}_2\text{C}_6\text{H}_5)_2$ . [130°] (S. a. P.); [128°] (Colson, *Bl.* [3] 1, 347). From hydroquinone,  $\text{KOH}$ , benzyl bromide, and alcohol. Tables (from alcohol). Insol. water and  $\text{KOH}$  aq.; sol. benzene, ether, and chloroform. Conc.  $\text{HNO}_3$  dissolves it, forming a nitro-derivative crystallising in lemon-yellow needles  $\text{C}_{22}\text{H}_{19}\text{NO}_5$ . [85°] (S. a. P.); [78°] (C.).

**Bromo-phenyl ether**  $\text{C}_6\text{H}_4(\text{OH})(\text{OC}_6\text{H}_4\text{Br})$ . Formed by the action of boiling  $\text{HBr}$  on a solution of *p*-diazophenol sulphate:

A pungent oil. Sol. alkalis, alcohol and ether. Its constitution is somewhat doubtful, as its vapour density has not been taken (Böhmer, *J. pr.* [2] 24, 479).

**References.**—AMIDO-, BROMO-, CHLORO-, IODO- AND NITRO-. HYDROQUINONE.

Dihydroquinone v. Tetra-oxo-diphenyl.  
HYDROQUINONE CARBOXYLIC ACID  
DI-OXO-BENZOIC ACID.

**Hydroquinone di-carboxylic acid v. Di-oxy-terephthalic acid.**

**Hydroquinone tetra-carboxylic acid**  $C_6H_2O_6$ , i.e.  $C_6H_2(OH)_4(COOH)_2$ , [1:4:2:3:5:6]. *Di-oxy-pyromellitic acid*. Obtained by saponifying the ether with KOHAq (Nef, A. 237, 52; C. J. 53, 428). Flat, pale yellow, needles (containing  $1\frac{1}{2}$  aq), v. sol. hot water, the yellow solution exhibiting green fluorescence.  $FeCl_3$  colours its solution blue. Nitric acid does not act on it in the cold, but on warming complete decomposition occurs. Chromic acid behaves in like manner.  $Na_2A''$ : characteristic faint yellow prisms, v. sl. sol. NaOHAq. —  $Ag_2A''$ : lemon yellow flocculent pp. The lead salt is a light yellow granular pp. The barium salt is a pale yellow granular pp.

**Ethyl ether**  $Et_2A''$ , [128°]. Formed by treating a solution of quinone tetra-carboxylic ether in HOAc with zinc-dust (Nef). Pale yellow needles, v. sol. alcohol, ether, and HOAc, the solutions exhibiting blue fluorescence. Crystallises in two forms, both monoclinic, viz.: (i.)  $a:b:c = 2.988:1.3060$ ;  $\beta = 64^\circ 36'$ ; and (ii.)  $a:b:c = 1.790:1.3321$ ;  $\beta = 81^\circ 53'$  (Groth). Its alcoholic solution is coloured bluish-green by  $FeCl_3$ . It dissolves in dilute NaOHAq. NaOEt gives a red colour. Nitric acid (S.G. 1.4) oxidises it to quinone tetra-carboxylic ether. Zinc and HCl reduce it to the following body.

**Dihydrate of hydroquinone tetracarboxylic ether**  $C_6H_4O_4$ , i.e.  $C_6H_4(OH)_2(COOEt)_2$ , *p-Diketomethylene tetracarboxylic acid*, [144°]. Formed by adding zinc-dust (10 g.) and conc. HCl to an alcoholic solution of the preceding ether (2 g.) (Nef). Colourless needles or prisms (containing 2aq). In the hydrated condition it is v. sol. alcohol and ether; in the anhydrous condition it is but slightly soluble in these liquids. Its solutions show feeble blue fluorescence. Its alcoholic solution is coloured cherry-red by  $FeCl_3$ . Bromine added to its solution in  $CS_2$  forms hydroquinone tetra-carboxylic ether. It reacts with phenyl-hydrazine and with hydroxylamine; and on this account its formula may also be written  $C_6H_4O_4(COOEt)_2$ , i.e. tetra-hydrate of quinone tetra-carboxylic acid. Hence Nef suggests that one of the two crystalline forms in which he obtained hydroquinone tetra-carboxylic ether may be the di-hydrate of quinone tetra-carboxylic ether  $C_6H_4O_4(COOEt)_2$ .

**HYDROQUINONE CARBOXYLIC ALDEHYDE v. Di-oxy-benzic aldehyde.****HYDROQUINONE-GLUCOSIDE v. ARBUTIN.****HYDROQUINONE-PHTHALEIN**  $C_{12}H_8O_4$ , i.e.

[227°]. Formed, together with quinizarin, by heating hydroquinone (2 mols.) with phthalic anhydride (1 mol.) and a quantity of  $SnCl_4$  equal to 18 times the weight of the mixture, the whole being heated at  $125^\circ$  for 18 hours (Grimm, B. 6, 506; Ekstrand, B. 11, 713). Tables (containing aq from water) or needles (from ether); sl. sol. hot water, v. sol. alcohol and ether. Crystallises from alcohol in needles (containing HOEt). Alkalis turn its aqueous solution deep violet. Bromine, added to its solution in HOAc, forms penta-bromo-hydroquinone phthalein  $C_{12}H_3Br_5O_4$  (above  $300^\circ$ ), a colourless crystalline

powder, insol. all ordinary solvents. It gives colourless solutions with alkalis.

**Di-acetyl derivative**  $C_{12}H_8O_4 \cdot 2Ac_2O$ , [230°].

Colourless crystals (from MeOH).

**Hydroquinone phthalin**  $C_{12}H_8O_4$ , [208° uncor.]. Formed by heating hydroquinone-phthalein for 4 hours with zinc-dust and aqueous NaOH. Crystallises from benzene in large tables (containing  $C_2H_5$ ). Its alkaline solutions are colourless.  $H_2SO_4$  forms a red liquid, whence water gives an olive-green flocculent pp. of hydroquinone-phthalidin, which dissolves in ether with green fluorescence. Hydroquinone-phthalin readily yields the corresponding phthalein when treated with oxidising agents.

**Di-acetyl derivative**  $C_{12}H_8O_4 \cdot 2Ac_2O$ , [191°].

Colourless prisms (from MeOH).

**HYDROQUINONE SULPHONIC ACID**

$C_6H_4(OH)_2SO_3H$ . Prepared by heating hydroquinone (1 pt.) with 8 pts. of  $H_2SO_4$  at  $50^\circ$  for 3 hours (Seyda, B. 10, 688). Crystalline solid. Gives a blue colouration with  $FeCl_3$ . By fusion with NaOH or by heating to  $180^\circ$  with aqueous or alcoholic  $NH_3$ , the  $HSO_3$  group is eliminated as sulphate and hydroquinone regenerated.

**Salts.** —  $A^K$ : long monoclinic crystals,  $a:b:c = 96:1.2256$ ;  $\beta = 107^\circ 23'$ ; v. sol. water, sl. sol. alcohol; reduces  $AgNO_3$ . —  $A_2Ba$ : amorphous powder, sol. water. —  $A_2Zn$  4aq: concentric needles, v. sol. water and alcohol.

**Hydroquinone disulphonic acid**

$C_6H_4(OH)_2(SO_3H)_2$ . Formed by treating quinic acid with fuming  $H_2SO_4$  (Hesse, A. 110, 195). Syrup; v. sol. water and alcohol, insol. ether. Solutions of its alkaline salts give a deep blue colour with  $FeCl_3$  and reduce  $AgNO_3$ . Converted into quinizarin by heating with phthalic acid and  $H_2SO_4$ . —  $K_2A''$  11aq: prisms. —  $CaA''$  3aq. —  $BaA''$  4aq: monoclinic prisms, m. sol. cold water. —  $A''(PbOH)$ .

**Hydroquinone-di-sulphonic acid**

$C_6H_4(OH)_2(SO_3H)_2$ . Prepared by heating hydroquinone (1 pt.) with 5 pts. of fuming  $H_2SO_4$  for 1 hour at  $100^\circ$ – $110^\circ$  (Seyda, B. 10, 690). Formed also by heating potassium thiocromate with water at  $135^\circ$  (Graebe, A. 146, 48). Long deliquescent needles. V. sol. alcohol, v. sl. sol. ether. Gives quinizarin when heated with phthalic acid and  $H_2SO_4$ .

**Salts.** —  $A''K$  4aq: long prisms, sol. hot water, sl. sol. cold water, insol. alcohol.  $FeCl_3$  colours its aqueous solution blue. It reduces a boiling solution of  $AgNO_3$ . —  $A''Na$ : white amorphous powder, sol. water, insol. alcohol. —  $A''Ba$  31aq: glistening needles or long prisms, sol. hot, sl. sol. cold, water, insol. alcohol. —  $A''Zn$  6aq: concentric needles or long prisms, sol. hot water.

**Hydroquinone-di-sulphonic acid**

$C_6H_4(OH)_2(SO_3H)_2$ . From *p*-diazophenol disulphonic acid (Wilsing, A. 215, 239). Does not crystallise. Gives with  $FeCl_3$  a violet colour. Reduces  $AgNO_3$ .  $BaCl_2$  and  $Pb(OAc)_2$  give pps. sol. HOAc aq.

**Salt.** —  $K_2A''$  aq.

**Hydroquinone-disulphonic acid. Di-methyl derivative**  $C_6H_4(OMe)_2(HSO_3)_2$ . Prepared by sulphonating the di-methyl ether of hydroquinone (Kariot, B. 18, 1678). Colourless deliquescent needles. V. a. sol. water and alcohol, insol. ether.

**Salts.**—A<sup>+</sup>K<sup>+</sup>: large colourless tables, sol. water. FeCl<sub>3</sub> colours its solution deep violet-blue.—A<sup>+</sup>(NH<sub>4</sub>)<sub>2</sub>: colourless soluble prisms.—Ba<sup>2+</sup>: white amorphous powder, v. sol. water, insol. alcohol.—A<sup>+</sup>Zn<sup>2+</sup>: felted needles.

**HYDRORETENEQUINONE** v. RETENE.

**HYDROSORBIC ACID** v. HEXENOIC ACID.

**HYDROSULPHIDES.** (*Sulphohydrates.*)

Compounds of an element or radicle with hydrogen and sulphur. The name is sometimes restricted to those compounds which on account of their reactions probably contain the group SH. The hydrosulphides are the sulphur analogues of the hydroxides. The name *sulphohydrates*, sometimes given to these compounds, is badly chosen, as it suggests a compound of water with a sulphur-containing substance. The hydrosulphides are not numerous. Many non-metallic sulphides combine with more positive sulphides to form salts the negative radicle of which is the non-metallic sulphide; such salts may be regarded as derivatives of acidic hydrosulphides; but very few of these hypothetical acidic hydrosulphides have been isolated. As<sub>2</sub>S<sub>3</sub>, for instance, combines with many metallic sulphides to form salts of the three classes As<sub>2</sub>S<sub>3</sub>.M<sup>+</sup>S, As<sub>2</sub>S<sub>3</sub>.3M<sup>+</sup>S, and As<sub>2</sub>S<sub>3</sub>.2M<sup>+</sup>S; the hydrosulphides of As<sup>+</sup> corresponding to these salts would be As<sub>2</sub>S<sub>3</sub>H<sub>2</sub> or As<sub>2</sub>S<sub>3</sub>SH, As<sub>2</sub>S<sub>3</sub>H<sub>3</sub> or As<sub>2</sub>(SH)<sub>3</sub>, and As<sub>2</sub>S<sub>3</sub>H<sub>4</sub> or As<sub>2</sub>(SH)<sub>4</sub>; but none of these hydrosulphides has been isolated. The compounds H<sub>2</sub>SH and CS(SH)<sub>2</sub> are acidic hydrosulphides. The metallic hydrosulphides which have been isolated, e.g. CaS.H<sub>2</sub>, BaS.H<sub>2</sub>, are few in number and on the whole unstable; the production of a hydrosulphide seems to be fairly characteristic of a markedly positive metal.

M. M. P. M.

**HYDROSULPHOCYANIC ACID** v. CYANIC (SULPHO) ACID, p. 303.

**HYDRO-TEREPHTHALIC ACID** v. *Hydrides* of TEREPHTHALIC ACID.

**HYDROTHYMOQUINONE** C<sub>10</sub>H<sub>8</sub>O<sub>2</sub>, i.e. C<sub>10</sub>H<sub>7</sub>Me(C<sub>2</sub>H<sub>5</sub>)(OH). Formed by reducing thymoquinone with SO<sub>2</sub> (Carstanjen, *J. pr.* [2] 3, 54; Lallemand, *A.* 101, 121; 102, 121). V. sl. sol. cold, m. sol. hot, water; v. sol. alcohol and ether. May be sublimed. Gives thymoquinone on oxidation. Its methyl ether constitutes 80 p.c. of the essential oil derived from the roots of *Arnica montana* (Sigel, *A.* 170, 363).

Sulphonic acid C<sub>10</sub>HMe(C<sub>2</sub>H<sub>5</sub>)(OH).SO<sub>3</sub>H. Potassium salt KA'. Formed by warming thymoquinone with aqueous K<sub>2</sub>SO<sub>3</sub> (Carstanjen, *J. pr.* [2] 15, 478). Crystalline. FeCl<sub>3</sub> colours its aqueous solutions emerald green, the colour changing to yellow. It reduces silver solution forming a mirror. Decomposed by boiling HClAq into H<sub>2</sub>SO<sub>4</sub> and hydrothymoquinone.

**HYDROTIGLIC ACID** v. VALEROIC ACID.

**HYDROTIC ACID** C<sub>2</sub>H<sub>3</sub>NO<sub>2</sub>. A syrupy acid occurring in perspiration (Favre, *J. pr.* 58, 365). Sol. alcohol.—AgA': v. al. sol. alcohol.

**HEXA-HYDRO-TOLUENE** v. TOLUENE HEXA-HYDRIDE.

**HYDROTOLUQUINONE** C<sub>10</sub>H<sub>7</sub>Me(OH). [125]. (N.); [128°] (Riedel, *B.* 18, 120).

**Formation.**—1. By reducing toluquinone with SO<sub>2</sub> (Nietzki, *A.* 215, 150).—2. By oxidising *p*-toluidine with chromic acid mixture (Nietzki,

*B.* 10, 1935).—3. By treating amido-*o*-cresol with nitrous acid (Neville & Winther, *C. J.* 41, 415; *B.* 15, 2979). Pearly plates. May be sublimed. V. e. sol. water, alcohol and ether, m. sol. benzene. Oxidised readily to toluquinone. In aqueous NaOH it forms a bluish-green solution, turning dark brown. Its ammoniacal solution turns brown in air. FeCl<sub>3</sub> gives a brownish-red colour. Bleaching powder gives a bluish-green colouration, turning brown. It combines with aniline, forming C<sub>10</sub>H<sub>7</sub>(OH)(NH<sub>2</sub>Ph), which crystallises in small white plates [85°], sol. water (Hebebrand, *B.* 15, 1974). With *p*-toluidine it forms in like manner C<sub>10</sub>H<sub>7</sub>(OH)(C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>), crystallising in pearly plates [90°].

**Di-ethyl derivative** C<sub>10</sub>H<sub>7</sub>(OAc)<sub>2</sub>. [52°]. C<sub>10</sub>H<sub>7</sub>(OH)(OMe).

**Mono-methyl ether** C<sub>10</sub>H<sub>7</sub>(OH)(OMe). [72°]. [240°–245°]. Formed, together with the di-methyl ether, by heating hydrotoluquinone (12 pts.) with NaOH (8 pts.), MeI (30 pts.) and MeOH (100 pts.) at 100°. Plates. Sol. NaOH aq.

**Di-methyl ether** C<sub>10</sub>H<sub>7</sub>(OMe)<sub>2</sub>. [150°]. [214°–218°]. Differs from the preceding ether in being volatile with steam and insol. alkalies. Oxidised by chromic acid to a compound C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>, crystallising from alcohol in thin, almost black, needles [153°], which may be reduced by aqueous ammonium sulphide to C<sub>10</sub>H<sub>7</sub>O, which separates from benzene in slender needles [173°]. The compound C<sub>10</sub>H<sub>7</sub>O<sub>2</sub> is converted by heating with conc. HClAq at 100° into MeCl and C<sub>10</sub>H<sub>7</sub>O<sub>2</sub> [232°], which separates from alcohol in plates (containing aq).

**Isotoluquinone** C<sub>10</sub>H<sub>8</sub>O<sub>2</sub>. [204°]. Formed by allowing toluquinone (2 pts.) to stand for 24 hours with a mixture of H<sub>2</sub>SO<sub>4</sub> (5 pts.) and water (5 pts.) and reducing the resulting isotoluquinone with SO<sub>2</sub> (Spica, *G.* 12, 225). Pearly needles, sol. benzene, v. e. sol. alcohol and ether. Reoxidised by moist air to toluquinone. As only one toluquinone is indicated by theory, this body is perhaps a polymeride thereof.

**HYDROXAMIC ACIDS** v. HYDROXYLAMINE DERIVATIVES.

**HYDROXIDES.** Compounds of an element or radicle with oxygen and hydrogen, not with water. The term is restricted by some chemists to compounds whose reactions indicate the presence of the group OH (v. HYDRATES). If an hydroxide is defined to be a compound of an element or radicle with the group OH, a classification of hydroxides may be made, on the basis of composition, into mono-, di-, . . . *n*-hydroxy compounds. Hydroxides vary much in properties; some are alkaline, e.g. KOH and NaOH some are acids, e.g. NO<sub>2</sub>OH and SO<sub>3</sub>(OH)<sub>2</sub>; some are neutral, e.g. H<sub>2</sub>O (cf. HYDRATES).

M. M. P. M.

**HYDROXONIC ACID** C<sub>2</sub>H<sub>3</sub>N<sub>3</sub>O<sub>6</sub>. An acid produced by the action of sodium-amalgam on acid potassium allantoxanate C<sub>2</sub>H<sub>3</sub>N<sub>3</sub>O<sub>6</sub>K (Ponmaroff, *J. R.* 11, 56). Heavy crystalline powder, m. sol. boiling water. Not affected by boiling HClAq or HNO<sub>3</sub>. HClAq at 150° forms C<sub>2</sub>H<sub>3</sub>N<sub>3</sub>O<sub>6</sub> and a little CO. Boiling brat water gives biuret, CO, and CO<sub>2</sub>. Alkali KMnO<sub>4</sub> oxidises it to allantoxanic acid (NH<sub>2</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>: small needles, sl. sol. cold water. E<sup>+</sup>A<sup>+</sup>: small prisms. S.I.B.—Na<sup>+</sup>A<sup>+</sup>—Ba<sup>2+</sup>A<sup>+</sup>

crystalline pp. —  $\text{MgA}^{\text{a}}$  4aq. —  $\text{PbA}^{\text{a}}$  11aq. —  $\text{AgA}^{\text{a}}$  3aq; crystalline pp.

#### HYDROXY. COMPOUNDS v. ORY. COMPOUNDS.

**HYDROXYL.** The radicle OH. This group occurs in alcohols and in most acids. Its presence in organic compounds is shown by the following reactions: 1. *Sodium* gives off hydrogen. — 2. *Zinc ethyl* gives off ethane (Japp, *C. J.* 87, 665). — 3. *FeCl<sub>3</sub>* gives off HCl. — 4. *AcCl* and *BaCl* react, giving off HCl, and forming acetyl and benzoyl derivatives of the substance. 5. *Ac<sub>2</sub>O* and *Ba<sub>2</sub>O* also form acetyl and benzoyl derivatives. The number of hydroxyls present may be determined by saponifying the acetyl derivative with standard alkali, and titrating the product with standard acid (Schiff, *B. 12*, 1532). Jackson & Rolfe (*Ann.* 9, 83) prefer to prepare the *p*-bromo-benzoyl derivative by means of *p*-bromo-benzoyl chloride or anhydride, and then to determine by analysis the percentage of bromine in the product. — 6. According to Landwehr (*B. 19*, 2726) if a substance is added in excess to 15 c.c. of a very dilute solution of ferric chloride (prepared by adding 2 drops of a 10 p.c. solution of  $\text{FeCl}_3$  to 60 c.c. of water), the production of a sulphur-yellow colour denotes the presence of hydroxyl.

Hydrogen dioxide has sometimes been termed hydroxyl.

**HYDROXYLAMINE**  $\text{NH}_2\text{OH}$ . (*Oxyammonia*). This base was prepared by Lossen in 1865 by reducing  $\text{C}_2\text{H}_5\text{NO}$ , by the action of Sn and  $\text{HClAq}$ . It is a product of the reduction of nitroparaffins and nitrolic acids, of  $\text{HNO}_2$ ,  $\text{HNO}$ , some nitrates and nitrites, and is also produced by the union of H with NO.  $\text{NH}_2\text{OH}$  has not been isolated; it is known only in aqueous solution.

**Formation.**—1. By the partial reduction of  $\text{HNO}_2$ , by Sn and certain other metals with  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{aq}$ , or by an acidified solution of  $\text{SnCl}_2$ . Divers (*C. J.* 43, 443) and Divers & Shimidzu (*C. J.* 47, 597) have examined the reaction of Sn, Zn, and some other metals on  $\text{HNO}_2\text{aq}$  in presence of HCl or  $\text{H}_2\text{SO}_4$ . They conclude that  $\text{NH}_2\text{OH}$  is a product of the interaction of both acids and the metal, and that it is not produced by the reducing action, on the  $\text{HNO}_2$ , of hydrogen formed by the reaction between the metal and the HCl or  $\text{H}_2\text{SO}_4$  present.  $\text{NH}_3$  is formed along with  $\text{NH}_2\text{OH}$ ; according to D. & S. the  $\text{NH}_3$  is a product of the reaction between the metal and  $\text{H}_2\text{O}$ . Von Dumreicher (*M.* 1, 724) found that  $\text{SnCl}_2$  in presence of HCl reduces  $\text{HNO}_2$  to  $\text{NH}_2\text{OH}$ ; Divers & Haga (*C. J.* 47, 628) find that if sufficient water is present to prevent any reaction between the HCl and  $\text{HNO}_2$ , no  $\text{NH}_2\text{OH}$  is produced; the  $\text{SnCl}_2$  thus appears to react with a product of the interaction of the two acids. — 2. By reducing  $\text{NH}_4\text{NO}_2$  by Sn and  $\text{HClAq}$  (Mauwens, *C. B.* 70, 147), or  $\text{NaNO}_2$  by the same reagents (Donath, *W. A. B.* [2nd part] 75, 566). — 3. By reducing NO by passing it into Sn and  $\text{HClAq}$ , or by reaction with  $\text{SnCl}_2$  and  $\text{HClAq}$  (Von Dumreicher, *M.* 1, 724; Divers & Haga, *C. J.* 47, 628). According to D. & S. there is no action between NO and acidified  $\text{SnCl}_2$  solution at  $100^\circ$ . — 4. By the action of Sn and HCl, or  $\text{SnCl}_2$  in  $\text{HClAq}$ , on  $\text{C}_2\text{H}_5\text{NO}$  (Lossen, *B.* [3] 1, 551). — 5. By reducing various nitro-

paraffins by Sn and HCl (Meyer & Lochee, *B.* 8, 315); also by reaction of nitroparaffins with  $\text{H}_2\text{SO}_4$  (Freibisch, *J. pr.* [2] 7, 480; 8, 816; *M. & L. Lc.*). — 6. By reducing nitrites of K or Na, and some other nitrites by  $\text{H}_2\text{S}$  (Divers, *C. J.* 43, 454; 51, 487). — 7. By reaction of conc.  $\text{HClAq}$  with fulminates (*v. p.* 817, *Reactions* 10 and 11).

**Preparation.**—1. A mixture of 120 grams  $\text{C}_2\text{H}_5\text{NO}$ , 400 grams granulated tin, and 800–1,000 c.c.  $\text{HClAq}$  S.G. 1.19, to which are added about 2,500–3,000 c.c. water, is placed in several large flasks; action proceeds without heating; the flasks are shaken from time to time; when the action ceases the contents of the flasks are mixed, at least an equal volume of water is added, and the Sn is added by passing in  $\text{H}_2\text{S}$ ; the filtrate from  $\text{SnS}$  is concentrated, at first over a flame, then off the water-bath;  $\text{NH}_4\text{Cl}$  separates out, then a compound of  $\text{NH}_2\text{OH}$  with  $\text{SnCl}_2$ ; these crystals are removed, and the mother-liquor is evaporated to a small bulk, when crystals of  $\text{NH}_2\text{OH} \cdot \text{HCl}$  mixed with  $\text{NH}_4\text{Cl}$  separate (the mother-liquor contains various compounds of Cl, and chlorides of Fe, &c., derived from the HCl or the Sn used). The crystals are shaken with a very little cold absolute alcohol, the liquid is poured off; a few drops more absolute alcohol are added, and again poured off; the crystals are now kept in contact with boiling absolute alcohol until they are dissolved, the liquid is filtered hot, and (while still hot) enough  $\text{FeCl}_3$  in alcohol is added to ppt. the  $\text{NH}_2\text{OH}$  as  $2\text{NH}_2\text{OH} \cdot \text{FeCl}_3$ ; the filtered liquid yields crystals of pure  $\text{NH}_2\text{OH} \cdot \text{HCl}$  on cooling; by evaporating the mother-liquid a further yield of crystals is obtained; these should be recrystallised from hot absolute alcohol. About 47 grams  $\text{NH}_2\text{OH}$  are obtainable by this process from 120 grams  $\text{C}_2\text{H}_5\text{NO}$  (Lossen, *A. Suppl.* 6, 220). To prepare the  $\text{C}_2\text{H}_5\text{NO}$ , for making  $\text{NH}_2\text{OH}$ , 400 grams  $\text{HNO}_2\text{aq}$  S.G. 1.4, which have been boiled for a few minutes with about 7 grams urea nitrate and allowed to cool, are mixed with 800 grams commercial absolute alcohol; 800 grams urea nitrate are added, and the whole is distilled from a tubulated retort until from  $\frac{1}{3}$  to  $\frac{2}{3}$  have distilled over, when a funnel with glass stopcock is placed in the tubulus of the retort, and a freshly prepared mixture of 400 g.  $\text{HNO}_2\text{aq}$  with 800 g. alcohol is allowed to flow into the retort, drop by drop, while distillation proceeds. The  $\text{C}_2\text{H}_5\text{NO}$ , thus obtained is washed with water, and then used as already described. — 2. Von Dumreicher (*Sitz. W.* 52, 560) recommends the reduction of  $\text{C}_2\text{H}_5\text{NO}$ , by a solution of  $\text{SnCl}_2$  in  $\text{HClAq}$ ; about 90 p.c. of the theoretical yield of  $\text{NH}_2\text{OH}$  is thus obtained.  $\text{C}_2\text{H}_5\text{NO}$ , is mixed with a solution of  $\text{SnCl}_2$  in conc.  $\text{HClAq}$  in the ratio shown by the equation

alcohol is added so as to make a homogeneous liquid, and after a little the whole is gently warmed until a little of the liquid gives a clear yellow pp. with  $\text{H}_2\text{S}$ . The Sn is removed by ppm. with  $\text{H}_2\text{S}$ , the filtrate is evaporated and treated as directed in 1. Instead of the tedious process of ppm. Sn by  $\text{H}_2\text{S}$ , and the long-continued evaporation of the filtrate, V. Meyer (*B. 16*, 2793) recommends to concentrate the liquid considerably,

## HYDROXYLAMINE.

and when cold to add excess of  $\text{Na}_2\text{CO}_3$  to filter from the pp. which contains Sn, and also Fe, Ca, &c., present as impurities, to carefully acidify with  $\text{HCl}$ , and evaporate on the water-bath; by treating the residue with hot absolute alcohol, filtering from  $\text{NaCl}$  and  $\text{NH}_4\text{Cl}$ , and cooling, crystals of  $\text{NH}_2\text{OH} \cdot \text{HCl}$  containing only about 10 p.c.  $\text{NH}_4\text{Cl}$  are obtained. These crystals are sufficiently pure for most purposes for which  $\text{NH}_2\text{OH}$  is used.—3. Ludwig a. Hein (*B.* 2, 671) pass  $\text{NO}$  (made from  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{FeSO}_4$ , and stored in a gasholder) through a series of bottles containing Sn and conc.  $\text{HClAq}$  to which a little  $\text{PtCl}_4$  has been added; the dissolved Sn is removed by ppn. as  $\text{SnS}$ ; the rest of the process is as described in 1. In this reaction some N is always produced, but  $\text{N}_2\text{O}$  is not formed (Divers a. Hager, *C. J.* 47, 623). If air is excluded no  $\text{NH}_3$  is produced according to D. a. H.; but Von Dumreicher (*M.* 1, 724) says that  $\text{NH}_3$  is formed by reduction of  $\text{NH}_2\text{OH}$  by the  $\text{SnCl}_4$ . 4.  $\text{NH}_2\text{OH}$  is not economically prepared by the reduction of  $\text{HNO}_3$ . In one case, however, Divers stained fully 80 p.c. of the  $\text{HNO}_3$  as  $\text{NH}_2\text{OH}$  (*J.* 43, 445); in this experiment 58 c.c. conc.  $\text{ClAq}$  were mixed with 5 c.c.  $\text{HNO}_3 \text{Aq}$  S.G. 1.42, and the mixture was at once poured on to 35 g. anulated tin in an atmosphere of  $\text{CO}_2$ , the flask being placed in cold water. If this method employed the liquid must be kept very decidedly acid throughout the reaction; about 5–6 g.  $\text{H}_2\text{SO}_4$  (supposing that acid to be used) should be present in every 100 c.c. liquid, the amount of  $\text{HNO}_3$  in 100 c.c. not exceeding 7 g. (Divers a. himidzy, *C. J.* 47, 597). Divers (*C. J.* 43, 58) has examined the action of various metals on a mixture of  $\text{HNO}_3$  and  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ .

$\text{NH}_2\text{OHAq}$  is obtained from one of the salts prepared as described, (i.) by forming the sulphate, by evaporating the other salt with an equivalent quantity of  $\text{H}_2\text{SO}_4$ , and crystallising from alcohol, and (ii.) by decomposing the sulphate in aqueous solution by an equivalent quantity of  $\text{BaO}_2$ , in solution, and filtering from  $\text{BaSO}_4$ .

**Properties.**— $\text{NH}_2\text{OH}$  has not been isolated. When  $\text{NH}_2\text{OHAq}$  is distilled  $\text{NH}_3$  and water pass over, the distillate also contains some  $\text{H}_2\text{O}$ .  $\text{NH}_2\text{OHAq}$  is colourless and odourless; it has an alkaline reaction, and acts as an energetic reducer. An alcoholic solution of  $\text{NH}_2\text{OH}$ , obtained by decomposing conc.  $2\text{NH}_2\text{OH} \cdot \text{H}_2\text{SO}_4 \text{Aq}$  by  $\text{KOH}$  in alcohol, reddens and inflames the skin.  $\text{NH}_2\text{OHAq}$  produces pps., insol. excess, in solutions of  $\text{ZnSO}_4$ ,  $\text{NiSO}_4$ ,  $\text{FeCl}_3$ ,  $\text{Alum}$ ,  $\text{CrAlum}$ , and  $\text{Pb}$  acetate; pps. are not produced from salts of  $\text{Mg}$ ,  $\text{Ca}$ ,  $\text{Sr}$ ,  $\text{Ba}$ .  $\text{NH}_2\text{OHAq}$  is unstable, it is decomposed by  $\text{KOH}$ .  $\text{NH}_2\text{OHAq}$  is distinctly basic; in its reactions with acids it resembles  $\text{NH}_3 \text{Aq}$ , both combine with the acids to form salts  $\text{M} \cdot \text{NH}_2\text{OH}$ ,  $\text{M} \cdot \text{H}_2\text{SO}_4$ , &c., when  $\text{M} = \text{NH}_2\text{OH}$  or  $\text{NH}_3$ . The heat of neutralisation of  $\text{NH}_2\text{OHAq}$  is considerably less than that of  $\text{NH}_3 \text{Aq}$ ; Thomsen (*Th.* 1, 405) gives these numbers: [ $2\text{NH}_2\text{OHAq} \cdot 2\text{HClAq}$ ] = 18,520; [ $2\text{NH}_2\text{OHAq} \cdot \text{H}_2\text{SO}_4 \text{Aq}$ ] = 21,580; the values for  $\text{NH}_3$  are 24,540 and 28,150 respectively. The introduction of the acidic group  $\text{OH}$  in place of  $\text{H}$  considerably decreases the basic character of the molecule. More heat is produced in the formation, from the elements, of an aqueous

solution of  $\text{NH}_2\text{OH}$  than of  $\text{NH}_3$ ; Thomsen's numbers are [ $\text{N} \cdot \text{H}_2\text{O} \cdot \text{Aq}$ ] = 24,290; [ $\text{N} \cdot \text{H}_3 \cdot \text{Aq}$ ] = 20,820; similarly with the hydrochlorides [ $\text{N} \cdot \text{H} \cdot \text{O} \cdot \text{Cl}$ ] = 76,510; [ $\text{N} \cdot \text{H} \cdot \text{Cl}$ ] = 75,790 (*Th.* 2, 84).

As  $\text{NH}_2\text{OH}$  cannot be gasified its molecular weight is unknown. Lossen has shown that there are three isomerides of the form  $\text{NRR} \cdot \text{OR}$ , and three of the form  $\text{NR} \cdot \text{B}_2 \cdot \text{OR}$ , where R is one monovalent radicle and  $\text{B}_2$  is another monovalent radicle. It appears then as if each H in  $\text{NH}_2\text{OH}$  were differently related to the rest of the molecule from the other H atom: the formula  $\text{NH}_2\text{OH}$ , however, shows two H atoms similarly related to the rest of the molecule. This formula is confirmed by the production of hydroxylamine by reducing nitrites ( $\text{NO}_2 \cdot \text{OH}$ ), and by the general reactions and combinations of the body. If the molecule of hydroxylamine is represented by the formula  $\text{HO} \cdot \text{H} \cdot \text{N} - \text{NH}_2 \cdot \text{OH}$ , the existence of all the observed isomeric derivatives is accounted for (*v.* **HYDROXYLAMINE DERIVATIVES**).

**Detection and Estimation.**—Traces of salts of  $\text{NH}_2\text{OH}$  ppt.  $\text{Cu}_2\text{O}$  from fairly conc.  $\text{KOH}$  or  $\text{NaOH}$  to which a little  $\text{CuSO}_4 \text{Aq}$  has been added (Lossen) [ $2\text{NH}_2\text{O} + 4\text{CuO} = \text{N}_2\text{O} + 2\text{Cu}_2\text{O} + 3\text{H}_2\text{O}$ ].  $\text{NH}_2\text{OH}$  may be estimated by titration with standard I, in presence of  $\text{MgO}$  added to neutralise  $\text{HI}$  [ $2\text{NH}_2\text{O} + 2\text{I} = \text{N}_2\text{O} + \text{H}_2\text{O} + 4\text{HI}$ ]; or by warming with solution of  $\text{Fe}_2(\text{SO}_4)_3$  to  $80^\circ\text{--}90^\circ$ , and determining the ferrous iron by standard  $\text{KMnO}_4 \text{Aq}$

(*v.* Meyerinhg, *B.* 10, 1940).

**Reactions.**—1.  $\text{NH}_2\text{OHAq}$  reduces many metallic salts in solution;  $\text{CuSO}_4 \text{Aq}$  gives a grass-green pp., becoming reddish on boiling  $\text{Cu}_2\text{O}$  ppts.; the pp. in the cold is sol. in excess of  $\text{NH}_2\text{OHAq}$ , access of air to the solution causes a brown-green pp. sol. on gently warming; ammoniacal  $\text{CuSO}_4 \text{Aq}$  is decolourised by  $\text{NH}_2\text{OHAq}$ ,  $\text{CuSO}_4$  with excess of  $\text{KOH}$  is reduced to  $\text{Cu}_2\text{O}$ ,  $\text{HgCl}_2 \text{Aq}$  is reduced to  $\text{HgCl}$ ;  $\text{AgNO}_3$  gives  $\text{Ag}$  with evolution of gas ( $\text{N}_2\text{O}$  and  $\text{N}$ ); salts of  $\text{Au}$  and  $\text{Pt}$  are reduced to metal, the latter on warming (Fremy, *C. R.* 40, 61, 1207; Lossen, *B.* 8, 357);  $\text{K}_2\text{CrO}_7 \text{Aq}$  is reduced, but only on warming, addition of a little  $\text{H}_2\text{SO}_4$  causes rapid evolution of gas and formation of a brown pp. (Lossen, *A. Suppl.* 6, 235). In these reactions the  $\text{NH}_2\text{OH}$  is generally completely decomposed to  $\text{H}_2\text{O}$ ,  $\text{N}_2\text{O}$ , and  $\text{N}$ ; according to Meyerinhg (*B.* 10, 1940) and Donath (*W. A. B.* 75 [2nd part], 566), only  $\text{N}_2\text{O}$  is evolved.—2. According to Von Dumreicher (*M.* 1, 724) acidified stannous chloride reduces  $\text{NH}_2\text{OH}$  to  $\text{NH}_3$  at  $100^\circ$ ; but Divers a. Haga (*C. J.* 47, 623) assert that no  $\text{NH}_3$  is produced if access of air is prevented.—3. *Time and hydrochloric acid* slowly reduce  $\text{NH}_2\text{OH}$  to  $\text{NH}_3$  (Lossen); according to Divers a. Haga (*Loc. cit.*) Sn and hot conc.  $\text{HClAq}$  have hardly any action on  $\text{NH}_2\text{OH} \cdot \text{HCl}$ ; Divers a. Shimidzu (*C. J.* 47, 597) say that  $\text{Zn}$  and  $\text{H}_2\text{SO}_4 \text{Aq}$  likewise have practically no action on  $2\text{NH}_2\text{OH} \cdot \text{H}_2\text{SO}_4$ .—4.  $\text{NH}_2\text{OHAq}$  and salts of  $\text{NH}_2\text{OH}$  are decomposed by potash with evolution of  $\text{N}$ ,  $\text{NH}_3$ , and a little  $\text{N}_2\text{O}$ .—5. Iodine quickly decomposes  $\text{NH}_2\text{OH}$  and its salts to  $\text{N}_2\text{O}$  and  $\text{H}_2\text{O}$  with formation of  $\text{HI}$ .—6. Ferric sulphate is reduced by  $\text{NH}_2\text{OH}$  and its

salts to  $\text{FeSO}_4$ , with evolution of  $\text{N}_2\text{O}$ .—7. Contact with *sine*, in absence of acid, decomposes  $\text{NH}_4\text{OH}$  and its salts (Divers a. Shimidzu, C. J. 47, 597).—8. Sodium nitrate causes evolution of  $\text{N}_2\text{O}$  from  $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ ; dilute solutions of  $\text{KNO}_3$  and  $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$  only react when boiled (V. Meyer, C. C. 1876, 820).

**Combinations.**— $\text{NH}_4\text{OH}$  combines with many acids to form salts. In these reactions  $\text{NH}_4\text{OH}$  behaves similarly to  $\text{NH}_3$ ; the acid and base combine, and the salt is the only product of the interaction. The salts of  $\text{NH}_4\text{OH}$  have the composition  $\text{BA}$ ,  $\text{B}_2\text{A}_{11}$ ,  $\text{B}_3\text{A}_{111}$ , where  $\text{B} = \text{NH}_4\text{OH}$ ,  $\text{A}_1 = \text{monobasic acid}$ ,  $\text{A}_{11} = \text{dibasic acid}$ ,  $\text{A}_{111} = \text{tribasic acid}$ . The salts of  $\text{NH}_4\text{OH}$  crystallise without water; they are easily decomposed by heat, generally with evolution of  $\text{N}$  and  $\text{N}_2\text{O}$ . The chief salts were acetate  $\text{NH}_4\text{OH} \cdot \text{C}_2\text{H}_3\text{O}_2$ , crystallises from warm absolute alcohol; hydrochloride  $\text{NH}_4\text{OH} \cdot \text{HCl}$ , crystallises from alcohol or water, melts at  $100^\circ$ , and then decomposes violently to  $\text{N}$ ,  $\text{HCl}$ ,  $\text{H}_2\text{O}$ , and  $\text{NH}_4\text{Cl}$ . V. Meyer (B. 15, 2789) says that the presence of 10–15 p.c.  $\text{NH}_4\text{Cl}$  in  $\text{NH}_4\text{OH} \cdot \text{HCl}$  is not objectionable for most purposes for which the salt is used, and that the salt is perfectly stable when it is mixed with some  $\text{NH}_4\text{Cl}$ . If, however, it should contain any  $\text{HCl}$  or  $\text{FeCl}_3$ , the whole of the  $\text{NH}_4\text{OH} \cdot \text{HCl}$  is slowly changed to  $\text{NH}_4\text{Cl}$ . Nitrate  $\text{NH}_4\text{OH} \cdot \text{HNO}_3$ , easily sol. in absolute alcohol; phosphate,  $\text{NH}_4\text{OH} \cdot \text{H}_3\text{PO}_4$ , separates in small crystals on mixing dilute solutions of  $\text{Na}_2\text{HPO}_4$ , and an easily sol. salt of  $\text{NH}_4\text{OH}$ ; sulphate  $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ , very sol. in water, pptd. by alcohol. Meyer (B. 10, 1946) describes some double salts: hydroxylamine alum ( $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ ),  $\text{Al}(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ , and a chrome-alum ( $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ ),  $\text{Cr}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ , and iron alum ( $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ ),  $\text{Fe}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ . These double salts are formed in octahedral crystals by mixing conc. solutions of their constituent salts and allowing to crystallise; the double salt ( $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ ),  $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$  was obtained by mixing solutions of the constituent salts.

M. M. P. M.

**HYDROXYLAMINE DERIVATIVES.** Hydroxylamine is a very important reagent in organic chemistry, since it reacts with aldehydes and ketones with elimination of water, forming the oxims (V. Meyer a. Janny, B. 15, 2783; 16, 168).

The oxims are also called isonitroso-compounds, and are frequently interchangeable with nitroso-compounds. Thus, nitroso-phenol is identical with the mono-oxim of quinone; and the oxim of pyruvic acid is identical with  $\beta$ -nitroso-propionic acid. The reaction of hydroxylamine on ketones sometimes does not take place where there are no hydrogen atoms attached to the carbon united with the carbonyl (Herzig a. Zeigel, B. 21, 3498).

Thioaldehydes react upon hydroxylamine in the same manner as aldehydes, producing the same compounds.

**Alkyl derivatives of hydroxylamine**

**Benzoyl derivatives**  $\text{BzNH} \cdot \text{OH}$ .

**Benzohydroxamic acid.** [158]. B. 32 at  $6^\circ$ . If hydroxylamine hydrochloride (1 pt.) be dissolved

in water, and the solution, after neutralisation with  $\text{NaOH}$ , be mixed with benzoyl chloride (8 pts.) in the cold, di-benzoyl-hydroxylamine separates while the benzoyl hydroxylamine which remains in solution may be pptd. as a Ba salt by baryta, and then liberated by  $\text{H}_2\text{SO}_4$  (Lossen, A. 161, 347). Trimetric plates (from alcohol);  $d_{20}^{20} = 1.3561$ ;  $n_D^{20} = 1.582$  (Klein, A. 166, 180). M. sol. water, v. e. sol. alcohol, al. sol. ether and  $\text{CS}_2$ , insol. benzene. Decomposed somewhat violently by heat. Acid in reaction. Boiling dilute  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  split it up into hydroxylamine and benzoic acid.

**Salts.**— $\text{BzNH} \cdot \text{OK}$  ( $\text{BzNH} \cdot \text{OH}$ ): trimetric prisms or plates, m. sol. warm water, al. sol. alcohol. Crystallises from an alcoholic solution even in presence of excess of caustic potash ( $\text{BzNH} \cdot \text{ONa}$ ) ( $\text{BzNH} \cdot \text{OH}$ ) 8aq; plates. Effloresces in dry air. Its aqueous solution gives white pps. with solutions of  $\text{CuSO}_4$ , alum,  $\text{MnCl}_2$ , and lead nitrate; a nearly white pp. with  $\text{CuSO}_4$ ; a green pp. with chrome alum; a whitish-green pp. with  $\text{NiSO}_4$ ; a peach-coloured pp. with cobalt nitrate; and a yellow pp. with mercuric chloride. All these pps. dissolve in excess. Silver nitrate gives a white pp., insol. excess, and rapidly blackening.  $\text{FeCl}_3$  gives a dark-red pp. dissolving in excess with formation of an intense red solution. This characteristic colouration is destroyed by conc.  $\text{HCl}$  but reappears on dilution.— $\text{Ba}(\text{ONH} \cdot \text{Bz})_2$ : minute needles, formed by neutralising the acid potassium salt with ammonia and ppg. with barium chloride.— $\text{Ba}(\text{ONH} \cdot \text{Bz})_2 \cdot (\text{HONH} \cdot \text{Bz})_2$ : crystallises in small prisms, together with free benzoyl-hydroxylamine, when the neutral Ba salt is decomposed by an insufficient quantity of  $\text{H}_2\text{SO}_4$ , and the filtrate is allowed to evaporate. V. al. sol. water and alcohol.— $\text{Ca}(\text{ONH} \cdot \text{Bz})_2$ : amorphous pp.— $\text{Zn}(\text{ONH} \cdot \text{Bz})_2$ : crystalline pp.

**Ethyl ether v. Ethyl-hydroxylamine** (*infra*).

**Di-benzoyl derivative**  $\text{Bz} \cdot \text{NOH} \cdot \text{Di-benzohydroxamic acid}$ . [158] (Steiner, A. 178, 226; cf. Heintz, Z. 275, 733). Formed by the action of  $\text{BzCl}$  on hydroxylamine or on benzoyl-hydroxylamine (Lossen). Formed also by treating nitro-ethane with  $\text{BzCl}$  and extracting the product with boiling benzene (Kessel, Bl. 21, 88, 171). Needles or prisms. Sl. sol. water, cold alcohol, ether, and  $\text{CS}_2$ , m. sol. hot alcohol, almost insol. benzene. Acid to litmus. Decomposes violently when heated above its melting-point, forming benzanilide, phenyl cyanate,  $\text{HOBz}$ , and  $\text{CO}$  (Pieschel, A. 175, 305). Boiling dilute acids split it up into hydroxylamine and benzoic acid. Boiling baryta-water forms benzoic acid and benzoyl-hydroxylamine.  $\text{FeCl}_3$  does not colour solutions of di-benzoyl-hydroxylamine, but in neutral solutions it gives a reddish-yellow pp. A solution of the K salt gives white pps. with nitrate of Pb, Ag, and Cu, with  $\text{MnCl}_2$ , with  $\text{ZnSO}_4$ , and with  $\text{CdSO}_4$ ; a bluish-green pp. with chrome alum; and an apple-green pp. with  $\text{NiSO}_4$ . Unlike mono-benzoyl-hydroxylamine it gives no pp. with salts of the alkaline earths.— $\text{Bz} \cdot \text{NOK}$ : thin pearly plates (from alcohol) or minute six-sided tables; decomposed by hot water into potassium benzoate, di-phenyl-urea, and  $\text{CO}_2$ ; and by  $\text{NaOH}$  into benzoyl-hydroxylamine and  $\text{NaOBS}$ .— $\text{Bz} \cdot \text{NONa}$ .— $(\text{Bz} \cdot \text{NO})_2$ .— $\text{Bz} \cdot \text{NOAg}$ .

Vol. II.

(7)-Modification [110]? Menoolinite  
 tables; separated from the crystals of the (8)-  
 variety by hand-picking. After fusion it takes a  
 long time to solidify, and then melts at 120°,  
 leaving perhaps being converted into the (8)-mo-  
 dification. Boiling dilute HCl (S.G. 1.05) forms  
 benzoic acid, benzoyl-anisyl-hydroxylamine, and  
 a quantity (40 p.c.) of the (8)-modification of  
 benzoyl-anisyl-benzoyl-hydroxylamine.

**Di-benzoyl-anisyl derivative**

$\text{Bz}_2\text{N.O.CO.C}_6\text{H}_4\text{.OMe}$ . Formed, in two modifications, by the action of anisyl chloride on di-benzoyl-hydroxylamine (Lossen, A. 186, 24).

(a)-Modification [110°]. Monoclinic needles or prisms. Boiling dilute HCl (S.G. 1.05) easily splits it up into anisic acid and di-benzoyl-hydroxylamine. Alcoholic KOH gives, on the contrary, benzoic acid and benzoyl-anisyl-hydroxylamine. Split up by heat into phenyl cyanate and benzoic anisic anhydride, together with smaller quantities of *p*-methoxy-phenyl cyanate and  $\text{Bz}_2\text{O}$ .

(β)-Modification [110°]. Rosettes of small crystals, occurring in the last crop of crystals of its (α)-isomeric form. It is scarcely attacked by boiling dilute HCl (S.G. 1.05); while prolonged heating with acid of S.G. 1.14 forms di-benzoyl-hydroxylamine, most of the substance being, however, converted into hydroxylamine, benzoic acid and anisic acid.

**Anisyl-di-benzoyl derivative**

$\text{MeO.C}_6\text{H}_4\text{.CO.NBz.OBz}$ ? Two modifications of this body are formed by the action of benzoyl chloride on silver anisyl-benzoyl-hydroxylamine (Lossen, A. 186, 25).

(a)-Modification [137°]. Monoclinic tables. Slowly decomposed by dilute HCl (S.G. 1.05), more readily by stronger HCl (S.G. 1.14), into benzoic acid and anisyl-benzoyl-hydroxylamine. Alcoholic KOH also gives benzoic acid and anisyl-benzoyl-hydroxylamine. When heated alone it yields *p*-methoxy-phenyl cyanate and  $\text{Bz}_2\text{O}$ , together with small quantities of phenyl cyanate and benzo-anisic anhydride.

(β)-Modification [110°]. Small rosettes. Not decomposed by HCl of S.G. 1.05, and only partially attacked by acid of S.G. 1.14. Alcoholic KOH forms anisyl-benzoyl-hydroxylamine.

**Anisyl-benzoyl-anisyl derivative**

$\text{C}_6\text{H}_4\text{(OMe).CO.NBz.O.CO.C}_6\text{H}_4\text{(OMe)}$ . Formed, in two modifications, by the action of anisyl chloride on the silver salt of anisyl-benzoyl-hydroxylamine.

(a)-Modification [153°]. Very small monoclinic tables (from ether);  $a:b:c = 866:1:380$ ;  $\beta = 75^\circ 22'$ . Dilute HCl (S.G. 1.05) easily decomposes it, forming anisic acid and anisyl-benzoyl-hydroxylamine. Alcoholic KOH forms, on the contrary, benzoic acid and di-anisyl-hydroxylamine.

(β)-Modification [149°]. Only 1 pt. of this modification is formed to 84 pts. of the preceding. It crystallises in monoclinic tables;  $a:b:c = 1002:1:789$ ;  $\beta = 89^\circ 51'$ .

**Di-anisyl-benzoyl derivative**

$\text{C}_6\text{H}_4\text{(OMe).CO.NOBz}$ ? [148°]. Formed, in only one modification, by the action of  $\text{BzCl}$  on silver di-anisyl-hydroxylamine. Monoclinic crystals. Slowly attacked by HCl of S.G. 1.05, more rapidly by stronger acid, forming benzoic acid and di-anisyl-hydroxylamine only. Alcoholic KOH reacts in like manner, but forms also a little anisic acid and anisyl-benzoyl-hydroxylamine.

**Benzoyl-di-anisyl derivative**

$\text{BzN(CO.C}_6\text{H}_4\text{.OMe).OBz}$ ? Formed, in two modifications, from the silver derivative of benzoyl-anisyl-hydroxylamine and anisyl chloride.

(a)-Modification [188°]. Triclinic prisms;

$a:b:c = 808:1:955$ ;  $\alpha = 99^\circ 45'$ ;  $\beta = 115^\circ 58'$ ;  $\gamma = 74^\circ 43'$ . Easily decomposed by HCl of S.G. 1.05 into anisic acid and benzoyl-anisyl-hydroxylamine. Alcoholic KOH acts in like manner.

(β)-Modification [188°]. Triclinic tables;  $a:b:c = 428:1:1400$ ;  $\alpha = 108^\circ 7'$ ;  $\beta = 96^\circ 18'$ ;  $\gamma = 89^\circ 25'$ . Behaves like the (α)-modification when treated with HCl or KOH.

**Cinnamoyl derivative**

$\text{C}_6\text{H}_5\text{.CH:CH.CO.NH.OH}$ . [110°]. Formed, together with the di-cinnamoyl derivative and cinnamic acid, by the action of cinnamoyl chloride on hydroxylamine in aqueous solution (Rostowski, A. 178, 218). Crystalline; sl. sol. cold, m. sol. hot, water v. sol. alcohol and ether, insoluble in benzene. Ferric chloride colours its solution deep violet.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).HCl}$ : very easily decomposable yellow crystals.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).HNA}$ : yellow plates.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).Ba}$ : sparingly soluble yellow crystalline powder which, when heated, gives off  $\text{CO}_2$  and  $\text{NH}_3$ .— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).Pb}$ : yellowish-white pp.

**Di-cinnamoyl derivative**

$\text{(C}_6\text{H}_5\text{.CH:CH.CO).N.OH}$ . [152°]. Formed as above. Prisms or laminae; sl. sol. ether, insol. water and baryta-water, v. sol. hot alcohol. Its salts when once separated from the aqueous solution are no longer soluble in water. The K salt is decomposed by boiling with water and converted for the most part into cinnamate. When the compound is heated to incipient carbonisation a resin is formed, from which small quantities of a crystalline powder  $\text{C}_{10}\text{H}_{11}\text{N}_2\text{O}_4$  may be extracted.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).NOx}$ : yellow powder.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).Pb}$ : amorphous yellowish pp.— $\text{(C}_6\text{H}_5\text{.CH:CH.CO.NH.OH).NOAg}$ : white pp.

**o-Amido-benzoyl derivative**

$\text{NH}_2\text{.C}_6\text{H}_4\text{.CO.NH.OH}$ . [82°]. From anthranil *o*-carboxylic acid and hydroxylamine. Glittering plates (from water) (E. von Meyer & Ballmann, J. pr. [2] 53, 20).

**(a)-Naphthoyl derivative**

$\text{C}_{10}\text{H}_7\text{.CO.NH.OH}$ . [187°]. From hydroxylamine and (a)-naphthoyl chloride (Ekstrand, B. 20, 1358). Glistening scales, sol. boiling water, almost insol. alcohol. Its potassium salt decomposes very readily with formation of (a)-naphthylamine.

**(β)-Naphthoyl derivative**

$\text{C}_{10}\text{H}_7\text{.CO.NH.OH}$ . [168°]. From hydroxylamine (1 mol.) and (β)-naphthoyl chloride (Ekstrand, B. 20, 1358). Small dimetric scales, v. sol. alcohol.

**Di-(a)-naphthoyl derivatives**

$\text{(C}_{10}\text{H}_7\text{.CO).N.OH}$ . [160°]. Formed, together with the mono-(a)-naphthoyl derivative (v. supra), by the action of (a)-naphthoyl chloride on hydroxylamine. Needles, sol. boiling alcohol. Its K salt crystallises in needles, sol. alcohol.

**Di-(β)-naphthoyl derivative**

$\text{(C}_{10}\text{H}_7\text{.CO).NOH}$ . [171°]. Formed like the preceding. Small needles. Forms a crystalline potassium salt.

**(aβ)-Di-naphthoyl derivative**

$\text{(C}_{10}\text{H}_7\text{.CO).NOH}$ . [160°]. From (β)-naphthoyl-hydroxylamine and (a)-naphthoyl chloride at 100°. Needles (from alcohol).

**Phthalyl derivatives**  $\text{C}_6\text{H}_4\text{.CO.NH.OH}$  [280°]. Formed by the action of phthalyl

chloride or of phthalic anhydride on hydroxylamine (Cohn, A. 205, 295; Lach, B. 16, 1781). Needles or plates (from alcohol); v. sl. sol. water, v. sol. boiling alcohol, insol. ether and benzene. KOHq dissolves it, forming a red solution. When boiled with KOH (1 mol.) dissolved in alcohol it is split up into CO<sub>2</sub> and o-amido-benzoic acid. When boiled with a larger quantity of KOH (2 mols.) in alcohol it gives the phthaloxyl derivative—C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>·NO<sub>2</sub>Na: red amorphous powder.—C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>·NO: red pp., obtained by adding caustic potash (1 mol.) to an alcoholic solution. Readily decomposed by treatment with water.—BaCl<sub>2</sub>·4(C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>·NO)<sub>2</sub>·Ba—(C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>·NO)<sub>2</sub>·Pb(OH)<sub>2</sub>·3aq: light-red pp.—C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>·NOAg: dark-red pp.

**Phthaloxyl derivative** CO<sub>2</sub>H·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>·NH<sub>2</sub>·OH. Formed from the phthalyl derivative by warming with alcoholic KOH. Its solution is acid in reaction, and gives a violet colour with FeCl<sub>3</sub>, but it quickly decomposes with separation of its anhydride, the phthalyl derivative.—KC<sub>8</sub>H<sub>4</sub>NO<sub>2</sub>: yellowish crystals (from water); v. e. sol. cold water.—PbC<sub>8</sub>H<sub>4</sub>NO<sub>2</sub>: white pp.

ALKYL DERIVATIVES OF HYDROXYLAMINE.

**Methyl-hydroxylamine** H<sub>2</sub>N(OMe). The hydrochloride forms pearly scales (148° uncor.); does not reduce alkaline solutions of copper. It is formed by boiling the methyl ether of the oxim of benzoic aldehyde with HCl (Petracek, B. 16, 827).—B<sup>+</sup>H<sub>2</sub>PtCl<sub>6</sub>: orange-red tables or prisms (Waldstein).

**Benzoyl derivative** BzMeN.OH. (65°). From di-benzoyl-methyl-hydroxylamine by warming with conc. KOHq and passing CO<sub>2</sub> into the product (Lossen & Zanni, A. 182, 226). Rectangular tables (from ether-benzene). Decomposed by HCl into hydroxylamine and methyl benzoate.

**Di-benzoyl derivative** BzMeNOBz. [α<sub>D</sub> -15°]. Formed by the action of MeI on an ethereal solution of potassium di-benzoyl-hydroxylamine. Oil.

**Ethylene-di-hydroxylamine.**

**Di-benzoyl derivative** (NBz<sub>2</sub>O)<sub>2</sub>C<sub>2</sub>H<sub>4</sub>. [148°]. Formed by boiling silver di-benzoyl-hydroxylamine with an alcoholic solution of ethylene bromide (Eiseler, A. 175, 342). Prisms, sf. sol. cold ether and alcohol; moderately stable towards KOHq.

**Ethyl-hydroxylamine** NH<sub>2</sub>·OEt or EtHN.OH. (68°). S.G. 1.2883. Formed by decomposing ethyl-benzoyl-ethyl-hydroxylamine with HCl, and liberated from its hydrochloride by conc. KOHq (Lossen & Zanni, A. 182, 223; Gürke, A. 205, 274). Combustible liquid, with powerful odour; miscible with water, alcohol, and ether. Alkaline in reaction. Gives a white pp. with silver nitrate, and on boiling reduction takes place with evolution of gas. When added in excess to cupric sulphate solution it forms a deep blue liquid, whence an apple-green pp. is formed on boiling, reduction not taking place. With HgCl<sub>2</sub> it gives a golden flocculent pp.—B<sup>+</sup>HCl<sub>6</sub> [138°]. Scales; obtained by heating ethyl-benzoyl-ethyl-hydroxylamine with HCl in ether. Volatile. HClq (S.G. 1.14) at 160° decomposes it into EtCl and hydroxylamine.—B<sup>+</sup>H<sub>2</sub>PtCl<sub>6</sub>: prisms; v. sol. water and alcohol.—B<sup>+</sup>H<sub>2</sub>SO<sub>4</sub>: v.

e. sol. water and alcohol.—B<sup>+</sup>H<sub>2</sub>CO<sub>3</sub>: colourless powder.

**Benzoyl-ethyl-hydroxylamine** NHBz.OEt. (65°). Formed by the action of EtI on potassium benzoyl-hydroxylamine (Waldstein, A. 181, 385); the proportions being: benzoyl-hydroxylamine (1 mol.), conc. alcoholic KOH (2 mols.), and EtI (1 mol.); after being left for 24 hours, with frequent agitation, the solution is filtered from KI, freed from alcohol by evaporation, dissolved in water, and subjected to a stream of CO<sub>2</sub>, and the NHBz(OEt) extracted with ether. The same compound is also formed by treating ethyl-hydroxylamine with benzoyl chloride (Gürke, A. 205, 278; Bertram, A. 217, 16); and by treating benzoic ether with hydroxylamine (Tiemann & Krüger, B. 18, 740).

**Properties.**—Triclinic crystals (from alcohol); a:b:c = 610:1:852; α = 109° 31'; β = 85° 32'; γ = 100° 31'. V. e. sol. ether and alcohol; m. sol. water. Soluble in aqueous KOH (1 mol.), forming a solution from which it is reprecipitated by CO<sub>2</sub> and by acids, and which gives pps. with salts of Ag, Hg, and Pb. Hot conc. HClq in sealed tubes splits it up into benzoic acid and ethyl-hydroxylamine hydrochloride. By heating alone to 190° it is converted into phenyl cyanate, benzamide, aldehyde, and alcohol. PCl<sub>5</sub> gives benzoyl-ethoxim chloride Ph.CCN.OEt. (230°).—BzAgN.OEt: white pp.

**Ethyl-benzoyl-hydroxylamine** EtNBz.OH.

(α)-Modification [542]. S.G. 1.208. S. (ligroin of S.G. 65) 1:3. Formed, together with KOBz, by heating (α)-di-benzoyl-ethyl-hydroxylamine with conc. KOHq. Formed also, together with the (β)-isomere, by treating benzamido-ethyl ether with conc. hydroxylamine hydrochloride (Lossen, B. 17, 1587). Monoclinic tables or prisms (from benzene-ether); a:b:c = 1.49:1.153; inclination of optical axes = 11°. V. sol. alcohol and ether, m. sol. water. Sol. KOHq, forming a solution which is ppr. by metallic salts. On heating with HClq it is resolved into hydroxylamine and benzoic ether. Decomposes at 180° into benzonitrile, BzOEt, alcohol, water, and nitrogen, with smaller quantities of benzamide, benzoic acid, and CO<sub>2</sub>.

(β)-Modification [68°]. S.G. 1.185. S. (ligroin of S.G. 65) 2:21. Formed as above, and by the action of boiling KOH (1 pt.) dissolved in water (1 pt.) upon (β)-di-benzoyl-ethyl-hydroxylamine (Gürke, M. 205, 286), and upon ethyl-benzoyl-anisyl-hydroxylamine (Pieper, A. 217, 5). Monoclinic crystals; a:b:c = 1.24:1.140; inclination of optical axes = 72° 5' (Tenne, A. 217, 5). Less soluble in alkalis than the (α)-modification. Decomposed by HCl, and by distillation, into the same products as the (α)-isomere.

**Anisyl-ethyl-hydroxylamine** (C<sub>6</sub>H<sub>5</sub>O)<sub>2</sub>EtNOH. (84°). From ethyl-hydroxylamine and anisyl chloride (Pieper, A. 217, 18). Monoclinic tables (from ether). Forms with KOH a salt. Conc. HCl gives anisic acid and ethyl hydroxylamine.

**Ethyl-anisyl-hydroxylamine** C<sub>6</sub>H<sub>5</sub>O·NH.OEt. (82°). Formed by treating anisyl-benzoyl-ethyl-hydroxylamine with conc. KOHq, and ppr. by CO<sub>2</sub> (Eiseler, A. 175, 388).

Crystals; v. s. sol. alcohol and ether. Split up by HCl into anisic ether and hydroxylamine.

*Di-benzoyl-ethyl-hydroxylamine*,  $\text{Bz}_2\text{N.OEt}$ . Two, or possibly three, modifications of this compound are formed in the reaction between silver di-benzoyl-hydroxylamine and EtI; the (a)-variety is formed in the greater quantity, and crystallises out first; only 2 or 3 p.c. of the (B)-modification is formed; there is perhaps also an oily variety (Gürke, A. 205, 280).

(a)-Modification [58°]. S.G. 1.243. Trimetric crystals;  $a:b:c = 697:1:591$ . V. sol. ether and alcohol, insol. benzene. Decomposes at 180° into benzoic acid, benzonitrile, and aldehyde. Conc. KOHAq converts it into benzoic acid and (a)-ethyl-benzoyl-hydroxylamine. Conc. HClAq gives benzoic acid, benzoic ether, and hydroxylamine (Eiseler, A. 175, 330).

(B)-Modification [63°]. S.G. 1.232. Formed as above. It is also the chief product of the action of BzCl on (a) or (B) ethyl-benzoyl-hydroxylamine. Triclinic crystals;  $a:b:c = 556:1:714$ ;  $\alpha = 118^\circ 25'$ ;  $\beta = 102^\circ 37'$ ;  $\gamma = 90^\circ 52'$ . More soluble in alcohol and ether than the (a)-modification; insol. ligroin. When heated it yields the same products as its isomeride, but requires a temperature of 225°. Conc. HClAq also acts upon it in the same way as upon the (a)-variety. KOHAq acts upon it with more difficulty than upon its isomeride, and produces (B)-ethyl-benzoyl-hydroxylamine.

*Benzoyl-ethyl-benzoyl-hydroxylamine* [49°]. From  $\text{NBzEtAgO}$  and BzCl (Lossen, B. 10, 222g); or from  $\text{NBzEtHO}$ , BzCl, and KOHAq (Pieper, A. 217, 8). Trimetric crystals;  $a:b:c = 624:1:2587$ . V. sol. alcohol or ether, insol. water & petroleum. Split up by HCl into benzoic acid and hydroxylamine.

*Benzoyl-anisyl-ethyl-hydroxylamine*  $\text{BzN}(\text{C}_6\text{H}_5\text{O})\text{OEt}$ . Formed, in two modifications, by the action of EtI on silver benzoyl-anisyl-hydroxylamine (Eiseler, A. 175, 326; Pieper, A. 215, 2).

(a)-Modification [74°] (P.); [69°] (E.). Monoclinic tables (from ether-benzene);  $a:b:c = 1:618:1:666$ . Decomposed by alcoholic KOH into potassium anisate and (a)-ethyl-benzoyl-hydroxylamine [64°]. HCl forms benzoic ether, anisic acid, and hydroxylamine.

(B)-Modification. Oil.

*Ethyl-benzoyl-anisyl-hydroxylamine*  $\text{EtNBz.OC}_6\text{H}_5\text{O}$ . [85°]. Formed by treating ethyl-benzoyl-hydroxylamine with anisyl chloride and aqueous KOH (Pieper, A. 217, 4). Monoclinic crystals (from ether);  $a:b:c = 748:1:803$ . With conc. KOHAq it gives (B)-ethyl-benzoyl-hydroxylamine [68°] and potassium anisate. On distillation it gives benzonitrile, anisic acid, and aldehyde.

*Anisyl-benzoyl-ethyl-hydroxylamine*  $\text{BzN}(\text{C}_6\text{H}_5\text{O})\text{OEt}$ . [79°]. Formed, together with an oily isomeride, by treating silver anisyl-benzoyl-hydroxylamine with EtI (Eiseler). Triclinic prisms. Decomposed by KOH into ethyl-anisyl-hydroxylamine and  $\text{KOEt}$ . HCl gives hydroxylamine, anisic ether, and benzoic acid.

*Benzoyl-ethyl-anisyl-hydroxylamine*  $\text{BzNEt.OC}_6\text{H}_5\text{O}$ . [64°]. From silver benzoyl-ethyl-hydroxylamine and anisyl chloride (Pieper, A. 217, 10). Triclinic crystals (from ether);

$a:b:c = 773:1:855$ . M. sol. alcohol and ether, insol. water and ligroin. Not attacked by a solution of 2 pts. of KOH in 8 pts. of water; but a solution of equal weights of potash and water forms potassium anisate and benzoyl-ethyl-hydroxylamine [67°]. Dilute HCl at 100° forms benzoic acid, anisic acid, and ethyl-hydroxylamine; a still more dilute acid gives anisic acid and benzoyl-ethyl-hydroxylamine [67°]. On distillation it is split up into anisic ether and phenyl cyanate.

*Anisyl-ethyl-benzoyl-hydroxylamine*  $\text{C}_6\text{H}_5\text{O.NEt.OBz}$ . [94°]. From anisyl-ethyl-hydroxylamine, BzCl, and the calculated quantity of aqueous KOH (Pieper, A. 217, 18). Monoclinic crystals (from ether). Sol. sol. alcohol or ether, insol. water or light petroleum. Hot conc. KOHAq gives anisyl-ethyl-hydroxylamine [84°] and benzoic acid. HCl at 100° acts similarly, the anisyl-ethyl-hydroxylamine being subsequently broken up into anisic acid and ethyl-hydroxylamine. On distillation it is decomposed, but not neatly.

*Phthalyl-ethyl-hydroxylamine*  $\text{C}_6\text{H}_4\text{C}_2\text{O}_2\text{NOEt}$ . [104°] (c. 270°). From silver phthalyl-hydroxylamine and EtI (Cohn, A. 205, 295). Trimetric needles, sol. ether and petroleum, insol.  $\text{Na}_2\text{CO}_3\text{Aq}$ . When heated with potash it yields ethyl- $\alpha,\beta$ -dibenzoyl acid. It resembles the nitrolic acids in giving a red colouration with alkalis.

*Methyl-ethyl-hydroxylamine*.

*Methyl-ethyl-benzoyl-hydroxylamine*  $\text{MeNEt.OBz}$ . Prepared by the action of EtI on methyl-benzoyl-hydroxylamine dissolved in alcoholic KOH. Oil, with pleasant odour. Decomposed by dilute HCl into methyl benzoate and ethyl-hydroxylamine.

*Benzoyl-methyl-ethyl-hydroxylamine*  $\text{BzNMe.OEt}$ . From silver benzoyl-ethyl-hydroxylamine (1 mol.) and MeI (1 mol.) in ether (Waldstein, A. 181, 393). Oil; miscible with alcohol and ether. Decomposed by hot dilute HCl.

*Ethyl-benzoyl-methyl-hydroxylamine*  $\text{EtNBzOMe}$ . Formed by the action of MeI on (a)-ethyl-benzoyl-hydroxylamine dissolved in alcoholic KOH. Oil. Decomposed by HCl into methyl-hydroxylamine and benzoic ether.

*Di-ethyl-hydroxylamine*  $\text{NEt}_2\text{OH}$  or  $\text{NEtHOEt}$ . Formed, together with hydroxylamine, by reducing nitric ether with tin and EtCl (Lossen, A. Suppl. 6, 238). Its hydrochloride remains in the mother-liquor, from which hydroxylamine hydrochloride has crystallised. The free base, separated from its salts by KOH and extracted by ether, is a strongly alkaline syrup, v. sol. water, not easily volatile with steam. Its aqueous solution forms with  $\text{FeCl}_3$ , chromalum, cobalt nitrate, and lead nitrate, pps. insoluble in excess and with  $\text{CuSO}_4$ , a bluish-white pp., dissolving in excess to a violet-brown solution. It reduces silver oxide on heating. It also reduces boiling aqueous  $\text{HgCl}_2$ .

Salts.— $\text{B}^+\text{HCl}$ : syrup.— $\text{B}^+\text{H}_2\text{PtCl}_6$ : orange-red crystals (from alcohol).— $\text{B}^+\text{H}_2\text{SO}_4$ : minute laminae; ppd. by ether from its solution in alcohol.— $\text{B}^+\text{H}_2\text{PO}_4$ : prisms (from water) or hair-like needles (from alcohol).— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ : stellate groups of prisms (from water) or minute needles (from boiling alcohol).— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ : prisms (from water); insol. alcohol.

**Benzoyl derivative**  $\text{Et}_2\text{NOBz}$  or  $\text{EtNBz.OEt}$ . (244° i.v.). S.G. 1.026. Formed by the action of  $\text{EtI}$  on ethyl-benzoyl-hydroxylamine dissolved in alcoholic  $\text{KOH}$ . Yellowish aromatic oil; v. sol. alcohol and ether. Resolved by heating with  $\text{HClAq}$  into benzoic ether and ethyl-hydroxylamine.

**Tri-ethyl-hydroxylamine**  $\text{NEt}_3\text{OEt}$ . S.G. 0.8935. Formed by mixing  $\text{ZnEt}_2$  with nitroethane and ether in an atmosphere of  $\text{CO}_2$ , and after a fortnight decomposing the product with water (Bevad, *J. R.* 20, 126). Oil; v. sl. sol. water, miscible with alcohol, ether, and benzene. Its salts are very hygroscopic, and reduce silver, cupric, and mercuric salts.— $\text{B}^+\text{H}_3\text{C}_2\text{O}_4^-$ .

#### Benzyl-hydroxylamine

(a) -modification  $\text{NH}_2\text{OCH}_2\text{Ph}$ . Formed by warming the benzyl derivative of the oxim of acetone with aqueous  $\text{HCl}$ ; thus:

$\text{Me}_2\text{C}(\text{NOC}_2\text{H}_5)_2 + \text{OH}^- \rightarrow \text{Me}_2\text{CO} + \text{H}_2\text{NOC}_2\text{H}_5$  (Janny, *B.* 16, 175). Formed also in like manner by treating the (a)-benzyl derivative of benzaloxim (a)-benzylidene-benzyl-hydroxylamine) with conc.  $\text{HClAq}$  (Beckmann, *B.* 22, 515). Hydrochloride  $\text{B}^+\text{HCl}^-$ . Soft, silvery plates, sl. sol. water, v. sl. sol. cold, v. sol. hot, alcohol. Acid in reaction. Sublimes between 230° and 260° without previous fusion. Readily condenses with benzoic aldehyde. Boiling  $\text{HI}$  converts it into iodo-benzene and  $\text{NH}_3$ . Ureide  $\text{NH}_2\text{CO.NH.CO.C}_2\text{H}_5$ . [139°] (Behrend & Leuchs, *B.* 22, 385).

(b)-modification  $\text{C}_6\text{H}_5\text{NH.OH}$ . [58°]. Obtained from the (b)-benzyl ether of benzaloxim by the action of conc.  $\text{HClAq}$  at a high temperature (Beckmann, *B.* 22, 514). Formed also by heating (b)-di-benzyl-hydroxylamine with conc.  $\text{HClAq}$  at 130° (Behrend & Leuchs, *B.* 22, 615). Needles (from petroleum-ether).— $\text{B}^+\text{HCl}^-$  [110°]. Broad needles, v. sol. cold alcohol, v. e. sol. water. Reduces Fehling's solution in the cold.

**Di-benzyl-hydroxylamine**  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N.OH}$  [123°] uncor. Prepared by heating for two hours on the water-bath a solution of 30 g. hydroxylamine hydrochloride, 60 g.  $\text{Na}_2\text{CO}_3$ , 10 aq and 30 g. benzyl chloride in water and sufficient alcohol to just dissolve the benzyl chloride; on cooling the product crystallises out (yield: 14 g.) (Schramm, *B.* 16, 2184; Walder, *B.* 19, 1626). It is perhaps accompanied by a more strongly basic isomeride (Behrend, *B.* 22, 385). Long white needles. V. sol. alcohol, ether, benzene, sl. sol. ligroin,  $\text{CS}_2$ ,  $\text{HOAc}$ , and hot water. Dissolves in  $\text{HCl}$  but not in  $\text{NaOH}$  or  $\text{NH}_3$ . Not decomposed by conc.  $\text{HClAq}$  at 130°. By long boiling with acetic acid saturated with  $\text{HCl}$  it is split up into benzaldehyde and benzylamine; acetyl chloride has the same effect. Boiled with alcoholic benzyl chloride it yields tri-benzyl-hydroxylamine  $(\text{Ph.CH}_2)_3\text{N.OCH}_2\text{Ph}$ . By the action of  $\text{PCl}_5$  and treatment with water di-benzylamine is formed, the reaction probably being:

$\text{MeI}$  and  $\text{NaOEt}$  gives a compound  $(\text{C}_6\text{H}_5)_3\text{N.OH}$  which appears to be the hydride of the anhydride  $(\text{C}_6\text{H}_5)_3\text{N.O.N}(\text{C}_6\text{H}_5)$ . Heated with ethyl iodide and alcoholic sodium ethylate it gives di-benzyl-ethylamine (c. 800°) and a base

$\text{C}_{12}\text{H}_{17}\text{N}$  which forms felted crystals [84°]. Propyl iodide and a solution of sodium in propyl alcohol give benzylamine, propyl ether, and a small quantity of benzylbenzoate. With a very dilute colourless solution of  $\text{FeCl}_3$  it gives a yellow colour on standing. By the action of nitrous acid without cooling, di-benzyl-nitrosamine is formed; when kept cold the product is the nitrous ether  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N.O.NO}$ : [84°] which crystallises from dilute alcohol in flat white needles; v. sol. alcohol and ether, sl. sol. ligroin, insol. water (Walder, *B.* 19, 3287).

**Salts**.— $\text{B}^+\text{HCl}^-$ : pearly plates.— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ : sparingly soluble brownish-red crystals.— $\text{B}^+\text{HCl}^- \text{HgCl}_2$ : white plates, sol. warm alcohol, nearly insol. water.—Picrate  $\text{B}^+\text{C}_6\text{H}_3(\text{NO}_2)_3\text{O}_2\text{H}^-$ : [151° cor.]; glistening yellow plates, v. sol. alcohol and ether, insol. water (Walder, *B.* 20, 1751).

**Anhydride?**  $\{(\text{C}_6\text{H}_5)_2\text{N}\}_2\text{O}$ . The hydroiodide ( $\text{B}^+\text{HI}^-$ ) [148°], erroneously called 'tetra-benzyl-oxy-ammonium iodide,' is formed by heating di-benzyl-hydroxylamine with methyl iodide; from this salt the base is obtained by the action of  $\text{Ag}_2\text{O}$ . Strongly alkaline colourless, very deliquescent crystals. V. e. sol. water, sl. sol. ether. Distills at a high temperature.— $\text{B}^+\text{H}_2\text{Cl}_2^-$ : pearly prisms, m. sol. water, insol. ether.— $\text{B}^+\text{HI}^-$ : see above.— $\text{B}^+\text{H}_2\text{I}_2^-$ : [27°]; white crystals.— $\text{B}^+\text{HNO}_3^-$ : [159°]; white flat needles, sl. sol. water.— $\text{B}^+\text{H}_2\text{SO}_4^-$ : [152°]; soluble prisms.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6^-$ : [152°]; small yellow needles, sl. sol. hot water, insol. cold water (Walder, *B.* 19, 3289).

**Acetyl derivative**  $(\text{C}_6\text{H}_5)_2\text{N.OAc}$ . [173°]. From di-benzyl-hydroxylamine (1 mol.) and  $\text{AcCl}$  (1 mol.). Feathery crystals (from dilute alcohol); m. sol. water, v. sol. alcohol.

**Benzoyl derivative**  $(\text{C}_6\text{H}_5)_2\text{NOBz}$ . [97°]. From di-benzyl-hydroxylamine and  $\text{BzCl}$  (Behrend & Leuchs, *B.* 22, 385). Needles (from alcohol). Converted by boiling alcoholic  $\text{KOH}$  into di-benzyl-hydroxylamine and benzoic acid.

(b)-modification  $\text{C}_6\text{H}_5\text{CH}_2\text{NH.OCH}_2\text{C}_6\text{H}_5$ . An oil, which accompanies the preceding. Cond.  $\text{HClAq}$  at 130° splits it up into benzyl chloride and the (b)-modification of benzyl-hydroxylamine (Behrend & Leuchs, *B.* 22, 615).

**Tri-benzyl-hydroxylamine**  $(\text{C}_6\text{H}_5\text{CH}_2)_3\text{N.OCH}_2\text{C}_6\text{H}_5$ . [112°]. Formed by boiling di-benzyl-hydroxylamine for a long time with an alcoholic solution of benzyl chloride (Walder). Behrend and Leuchs (*B.* 22, 618) could only obtain by this method an oily tri-benzyl-hydroxylamine of basic character, mixed with an indifferent, probably isomeric, oil. Short white prisms, v. sol. alcohol and ether, insol. water.

**Salts**.— $\text{B}^+\text{HCl}^-$ : [172°]; white crystals, sl. sol. water, insol. ether.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6^-$ : [c. 150°]; small reddish-yellow crystals, sl. sol. alcohol (Walder, *B.* 19, 1631; cf. Behrend, *B.* 22, 385).

**Tri-benzyl-hydroxylamine**  $(\text{C}_6\text{H}_5\text{CH}_2)_3\text{N.OCH}_2\text{C}_6\text{H}_5$ . Formed together with di-benzyl-hydroxylamine, by the action of an alcoholic solution of benzyl chloride (3 mols.) on benzyl-hydroxylamine hydrochloride in presence of  $\text{Na}_2\text{CO}_3$ . Dilute  $\text{HClAq}$  dissolves the di-benzyl-hydroxylamine, but not the tri-benzyl-hydroxylamine, since the hydrochloride of this

## HYDROXYLAMINE DERIVATIVES.

is decomposed by water. The tri-benzyl derivative is then extracted with ether (Behrend *Lenchs*, B. 22, 614). Oil. With conc. HCl aq. 160° it gives di-benzyl-hydroxylamine [123°].

Salts.—B·HCl: [31°]; needles.—B·H<sub>2</sub>·PtCl<sub>6</sub>: [57°]; prisms, v. sl. sol. cold alcohol. — iorate: [132°]; v. sl. sol. water.

### Tri-nitro-phenyl-hydroxylamine

H<sub>2</sub>(NO<sub>2</sub>)<sub>3</sub>·NH<sub>2</sub>·OH. [100°]. Formed by the action of picric ether C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>3</sub>·OEt on hydroxylamine (Michael & Browne, J. pr. [2] 35, 58). Silky needles. Its solution is turned brown by the least trace of ammonia.

### Hexa-nitro-di-phenyl-hydroxylamine

C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>3</sub>·NH<sub>2</sub>·OH. Di-picryl-hydroxylamine. [70°]. Formed by adding picryl-chloride H<sub>2</sub>(NO<sub>2</sub>)<sub>3</sub>·Cl in alcoholic solution to an aqueous solution of hydroxylamine (M. a. B.). Yellow crystals, which may be sublimed.

Benzylidene-hydroxylamine C<sub>6</sub>H<sub>5</sub>·CH:NOH is described as BENZALDOXIM, v. vol. 1. p. 447. According to very recent researches of Beckmann B. 22, 432), when HCl is passed into an ethereal solution of benzaldoxim there is obtained an isomeride. This (β)-benzaldoxim yields the same products on treatment with HCl as the ordinary (α)-benzaldoxim, and both their ethyl ethers are oily and are split up by HCl into EtCl, H<sub>2</sub>Cl, and benzoic acid. The benzyl ethers of the two oxims, however, are different.

### (α)-Benzylidene-benzyl-hydroxylamine

C<sub>6</sub>H<sub>5</sub>·CH:NOC<sub>6</sub>H<sub>5</sub>. Formed, at ordinary temperatures, by the action of benzyl chloride on an alcoholic solution of (α)-benzaldoxim. Oil. Insol. water, sol. alcohol, and ether. Split up by HCl into benzyl chloride, benzoic acid, and H<sub>2</sub>Cl; but under certain conditions it yields benzoic aldehyde and (α)-benzyl-hydroxylamine.

### (β)-Benzylidene-benzyl-hydroxylamine

C<sub>6</sub>H<sub>5</sub>·CH:NOC<sub>6</sub>H<sub>5</sub> or C<sub>6</sub>H<sub>5</sub>·CH<O—NC<sub>6</sub>H<sub>5</sub>>. [82°]. Formed by the action of benzyl chloride upon (β)-benzaldoxim dissolved in alcohol containing NaOEt. Formed also from (α)-benzyl-hydroxylamine and benzoic aldehyde. Slender needles (from ether). It forms a crystalline hydrochloride [148°]. On treatment with HCl it yields benzoic aldehyde and (β)-benzyl-hydroxylamine.

Other derivatives of hydroxylamine are described as oxims of aldehydes, ketones, and ketonic compounds generally, and as nitroso-, isonitroso-, or oximido- compounds.

## HEXA-HYDRO-XYLENE v. XYLENE HEXAHYDRIDE.

### HYDRO-*o*-XYLOQUINONE

C<sub>6</sub>H<sub>4</sub>Me<sub>2</sub>(OH)<sub>2</sub> [1:2:3:6]. [221°]. Formed by reducing *o*-xyloquinone with SO<sub>2</sub> (Nörling & Forel, B. 18, 2678). Separates from water in crystals. Partially decomposed on melting.

### Hydro-*m*-xyloquinone

C<sub>6</sub>H<sub>4</sub>Me<sub>2</sub>(OH)<sub>2</sub> [1:3:2:5]. [151°]. Obtained by reducing *m*-xyloquinone (Nörling & Th. Baumann, B. 18, 1161).

Hydro-*p*-xyloquinone C<sub>6</sub>H<sub>4</sub>Me<sub>2</sub>(OH)<sub>2</sub> [1:4:2:5]. *Hydrophlorone*. [212°] (N.); [208°] (Carstensen, J. pr. [2] 23, 421). Obtained by passing SO<sub>2</sub> into a saturated aqueous solution of *p*-xyloquinone (phlorone) (Von Rad, A. 151, 164; Nieszkzi, B. 13, 472). Colourless pearly

plates (from water). May be sublimed. Sl. sol. cold, m. sol. hot water; v. sol. alcohol and ether; m. sol. boiling benzene. FeCl<sub>3</sub> and other oxidising agents readily re-convert it into *p*-xyloquinone. Ammonia turns its solutions brown. It reduces boiling cupric acetate solution with ppn. of Cu<sub>2</sub>O. It reduces silver nitrate.

*Di-ethyl ether* C<sub>2</sub>H<sub>5</sub>Me<sub>2</sub>(OEt)<sub>2</sub>: [106°]; glittering plates (from alcohol) (Staedel & Hölz, B. 18, 2919).

### HYDROVIC ACID v. PTAHOVIC ACID.

### HYDURIC ACID, C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O<sub>4</sub>, &c.

*Formation*.—1. Discovered by Schlieper (A. 56, 11) among the products of the action of dilute nitric acid on uric acid, being found on one occasion in the mother liquor from which alloxan had crystallised. He was, however, unable to repeat the experiment.—2. By heating dialuric acid with glycerin (which acts merely as a solvent) at 160°, the products being acid ammonium, hydruilic, formic acid, and CO<sub>2</sub>, thus:

5C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O<sub>4</sub> = 2C<sub>6</sub>H<sub>4</sub>(NH)<sub>2</sub>N<sub>2</sub>O<sub>4</sub> + H<sub>2</sub>CO<sub>3</sub> + 3CO<sub>2</sub> (Baeyer, A. 127, 11).—3. By heating air-dried alloxan at 170°, the products being hydruilic acid, formic acid, CO<sub>2</sub>, ammonia, and CO (Murdock & Doeber, B. 8, 1872). The same products are obtained by heating air-dried alloxantin for three or four hours in a sealed tube at 170°.

4. Among the products obtained by passing H<sub>2</sub>S for several hours through a boiling solution of alloxantin.—5. By heating uric acid with H<sub>2</sub>SO<sub>4</sub> at 130°, glycocoll being also formed, whilst CO<sub>2</sub> is given off (Schultzen & Filehne, B. 1, 150).—6. By treating di-bromo-barbituric acid with a small quantity of HI (Baeyer, A. 130, 133).

*Preparation*.—9 pts. of perfectly dry dialuric acid are mixed in a capacious flask with 5 pts. of glycerin, and heated in an oil-bath to 140°–150°. A brisk and regular evolution of carbonic anhydride then takes place, and as soon as this ceases, and the contents of the flask have become solid, the temperature is raised for a short time to 160°, and the glycerin, after cooling, is removed by washing. A yellowish-white granular powder is then left, consisting of acid hydruilic of ammonium. To obtain the free acid the crude ammonium salt is dissolved in boiling water, ammonia is added in slight excess, and solution of cupric sulphate is added to the filtrate. The liquid then assumes a dark-green colour, and, if hot, deposits on cooling red warty crystals of neutral hydruilic of copper. This salt is then decomposed by hot hydrochloric acid, and the hydruilic acid which crystallises out is washed with dilute hydrochloric acid and dried over the water-bath.

*Properties*.—Crystallises from water in small four-sided prisms (containing 2aq). From a concentrated solution in HCl aq. or from an ammoniacal solution by ppn. by FeCl<sub>3</sub> it separates as a crystalline powder composed of small tablets (containing aq). V. sl. sol. cold, m. sol. hot water & v. sl. sol. alcohol. Dissolves in conc. H<sub>2</sub>SO<sub>4</sub>, and is reprecipitated on adding water. Scarcely sol. aqueous HCl. Not attacked by reducing agents. Not attacked by aqueous alkalis. Melting potash slowly forms oxalic acid. Gives a dark-green colour with FeCl<sub>3</sub>. This colour is

## HYMENODICTYONINE

also given by its soluble salts, but is destroyed by strong acids and alkalis; heat also destroys it, changing it to red.

**Reactions.**—1. When heated with *ferric chloride* it yields oxy-hydurilic acid, characterised by producing a blood-red colour with ferric salts.—2. HCl mixed with KClO<sub>4</sub> forms di-chloro-hydurilic acid.—3. Fuming *nitric acid* gives only alloxan; nitric acid of S.G. 1.4 gives alloxan, violuric acid (nitroso-barbituric acid), violantin, and dilituric acid, the last named being the ultimate product when heat is employed.

**Salts.**—Hydurilic acid is dibasic. It is a strong acid, and can decompose metallic chlorides, expelling HCl and forming acid salts. It dissolves readily in aqueous alkalis, and the solutions give pps. with metallic salts; the pps. are, however, acid salts. The neutral salts must be prepared from the free acid. HCl added to solutions of salts of hydurilic acid ppts. the acid as a chalk-white amorphous powder, which, when placed in hot water or hot HClAq, becomes crystalline.—NH<sub>4</sub>HA: small octahedra (by ppn. of an ammoniacal solution by acetic acid). M. sol. boiling water, separating as granules and crusts on cooling.—(NH<sub>4</sub>)<sub>2</sub>A: aq: needles, separating on rapidly cooling a hot saturated solution. Obtained in the same town by ppn. with ammonium sulphide, in which it is insoluble.—(NH<sub>4</sub>)<sub>2</sub>A<sup>2</sup>aq: large shining monoclinic efflorescent prisms, obtained by slow evaporation; m. sol. water, v. sol. aqueous NH<sub>3</sub>, but reppd. by alcohol.—NaA<sup>2</sup>aq: small prisms; obtained by dissolving the acid in NaOH aq, acidulating with acetic acid, and ppg. with alcohol.—BaA<sup>2</sup>aq: amorphous pp., soon becoming crystalline, got by adding a hot solution of hydurilic acid to barium acetate.—CaH<sub>2</sub>A<sup>2</sup>aq: small shining prisms, which separate when hydurilic acid is added to a solution of CaCl<sub>2</sub>.—CaA<sup>2</sup>aq: amorphous pp., soon becoming crystalline, obtained by decomposing calcium acetate by hydurilic acid.—CuH<sub>2</sub>A<sup>2</sup>aq: Obtained by mixing the acid with cupric acetate or with cupric sulphate. Separates from concentrated solutions in green needles, from more dilute solutions in yellow prisms. When heated the anhydrous salt is left as a red powder, which may also be obtained by ppn. from hot solutions.—CuA<sup>2</sup>aq: Obtained by adding the acid to excess of cupric acetate, or by mixing the neutral ammonium salt with cupric sulphate. From cold solutions it is pps. in short red needles of the hydrated salt; from warm concentrated solutions as a brownish-red pp. of the anhydrous salt.—ZnH<sub>2</sub>A<sup>2</sup>: feathery groups of lustrous needles, which separate when a solution of ZnCl<sub>2</sub> is mixed with hydurilic acid.—ZnA<sup>2</sup>aq: white amorphous pp., soon becoming crystalline.

Di-chloro-hydurilic acid OH.Cl.N<sub>2</sub>O<sub>2</sub>. Prepared by adding KClO<sub>4</sub> in small portions to a pasty mixture of hydurilic in conc. HClAq. Snow-white powder; v. sl. sol. water. Purified by dissolving in H<sub>2</sub>SO<sub>4</sub> and reppg. by water, when it separates as small trimetric crystals (containing 2aq.). Warm nitric acid slowly converts it into dilituric acid.—K<sub>2</sub>A<sup>2</sup>aq: small six-sided tables (from water); sl. sol. cold water.

**HYGRINE.** A volatile alkaloid said to accompany cocaine in coca leaves (Wöhler & Lossen, A.

121, 874). The leaves are exhausted with distilled water at 70°, the extract pps. with lead acetate, freed from lead by ppn. with aqueous Na<sub>2</sub>SO<sub>3</sub>, rendered slightly alkaline by Na<sub>2</sub>CO<sub>3</sub>, and extracted with ether. The ether extracts cocaine, and the residual solution be now rendered strongly alkaline by Na<sub>2</sub>CO<sub>3</sub>, ether will extract hygrine together with a neutral oil. These may be partially separated by distillation in a current of hydrogen, the greater part passing over below 140° (Lossen). Thick yellow oil, with strong alkaline reaction, burning taste, and characteristic smell resembling tri-methylamine. Fumes with HCl. Slightly volatile with steam. M. sol. water, sol. alcohol and ether. Its aqueous solution gives a white pp. with SnCl<sub>4</sub>, and a light blue pp. with CuSO<sub>4</sub>, not reduced on boiling. It also ppts. HgCl<sub>2</sub> and AgNO<sub>3</sub>. It forms a deliquescent hydrochloride, the aqueous solution of which gives a brown pp. with iodine in KI; a white pp. with HgCl<sub>2</sub>; yellowish flakes with PtCl<sub>4</sub>; a yellow powder with picric acid; and a white pp. with tannin. The platinochloride is decomposed by boiling water (O. de Coninck, B. [2] 45, 131). The above are the properties of the hygrine described by Lossen, who states that it is not poisonous. Stockman (Ph. [3] 18, 701) found in dried coca leaves a very minute amount of an oily alkaloid with burning taste and strong odour, which, however, was very poisonous. W. C. Howard (Ph. [3] 18, 71) obtained, by adding PtCl<sub>4</sub> to a solution of crude cocaine, a semi-crystalline pp. insoluble in water at 80°; this platinochloride contained 18.5 p.c. Pt and yielded a base that gave no crystallisable chloride, did not smell of trimethylamine, and had a bitter taste. Hesse (Pharm. Zeit. 1887, 669) came to the conclusion that hygrine was tri-methyl-quinoline, but he worked with only a few grammes of the substance. According to Liebermann (B. 22, 875) the so-called hygrine is a mixture of oxygenated bases. He found that crude hygrine, a very dark liquid smelling like piperidine and nicotine, was strongly alkaline, and almost entirely soluble in water. After dissolving in ether, drying with sticks of KOH, and fractionally distilling under 50 mm. pressure, two colourless liquids are obtained, boiling under 50 mm. pressure at 128°–131° and 215° respectively, and having the constitution C<sub>8</sub>H<sub>11</sub>NO and C<sub>8</sub>H<sub>9</sub>N<sub>2</sub>O.

Base C<sub>8</sub>H<sub>11</sub>NO. (c. 130° at 50 mm.); (194° cor. at 760 mm.). S.G.  $\frac{1}{4}$  0.40. V.D. (H=1) 68. This base, which is isomeric with tropine, may be distilled in a current of nitrogen.—B'C<sub>8</sub>H<sub>9</sub>(NO)<sub>2</sub>OH: (148°); yellow needles, m. sol. cold water.

Base C<sub>8</sub>H<sub>9</sub>N<sub>2</sub>O. (215° at 50 mm.). S.G.  $\frac{1}{4}$  0.82. Decomposed by distillation under atmospheric pressure.—Salts.—B'CH<sub>2</sub>Cl (dried at 100°): white crystalline powder.—B'CH<sub>2</sub>AuCl<sub>2</sub>: egg-yellow pp.—B'(C<sub>2</sub>H<sub>5</sub>(NO)<sub>2</sub>)OH: crystals (from boiling water); v. sl. sol. cold water.—Methylo-iodide B'MeI: white crystalline powder.

**HYMENODICTYONINE** C<sub>8</sub>H<sub>9</sub>N<sub>2</sub>. An alkaloid contained in the bark of *Hymenodictyon ecleusum* from which it may be obtained by mixing with lime and extracting with chloroform (Naylor, Ph. [3] 18, 817–818, 196). By extremely slow evaporation of its ethereal solu-

tion it may be obtained in a crystalline form, but otherwise it is an amorphous deliquescent mass. Its solutions are alkaline in reaction, have a persistent bitter taste, and are optically inactive. Its hydrochloride gives pps. with the usual alkaloidal reagents. Conc.  $H_2SO_4$  gives a lemon-yellow colour changing to wine-red with bronzy lustre.— $B''H_2PtCl_6$ : yellow amorphous powder.— $B''H_2Cl$ .

*Ethyliodide*  $B''EtI$ : rosettes of needles (from alcohol).

**HYOCAFFEINE** v. **CAFFEINE**.

**HYOCHOLIC ACID**  $C_{12}H_{21}O_6$ . An acid obtained together with glycocholl. by boiling hyoglycocholic acid with aqueous KOH (Strecker, A. 70, 191). Granules (from ether). Scarcely sol. water, v. sol. alcohol and ether. The solution of its ammonium salts is ppd. by solutions of metallic salts.— $BaA'$ , (dried at  $180^\circ$ ). Sl. sol. water, sol. alcohol.

$\beta$ -Hyocholic acid  $C_{12}H_{21}O_6$ . An acid obtained in like manner from ( $\beta$ )-hyoglycocholic acid (Jolin, H. 13, 205). It differs from the preceding chiefly in requiring a larger amount of  $Na_2SO_4$  or  $NaCl$  to ppt. its sodium salt from aqueous solution.

**HYODYSLYSIN**  $C_{12}H_{21}O_6$ . An amorphous substance, homologous with dyslysin, produced by the continued action of boiling hydrochloric acid on hyoglycocholic acid (Strecker, A. 70, 189). Insol. water, KOH aq. and aqueous  $NH_3$ , sl. sol. boiling alcohol, m. sol. ether.

**HYOGLYCOCHOLIC ACID**  $C_{12}H_{21}NO_6$ . Occurs as sodium salt, together with a smaller quantity of hyotaurocholic acid, in pigs' bile (Strecker a. Gundelach, A. 62, 205).

*Preparation*.—Fresh pigs' bile is completely saturated with  $Na_2SO_4$ ; the mixture is heated for some hours, and then left to cool. The resulting pp. is washed with a conc. solution of  $Na_2SO_4$ , dried at  $110^\circ$ , and treated with absolute alcohol. The alcoholic solution of sodium hyoglycocholate is decolourised with animal charcoal, and the salt ppd. by ether. The aqueous solution of the sodium salt is ppd. by  $H_2SO_4$ , and the pp. dissolved in alcohol and thrown down again with water. The acid separates in transparent drops.

According to Jolin (H. 11, 417) hyoglycocholic acid is accompanied by a smaller quantity of a ( $\beta$ )-isomeride, the sodium salt of which is less readily ppd. by  $Na_2SO_4$ . A solution of  $Na_2SO_4$ , saturated at  $0^\circ$  ppts. Strecker's acid only.

*Properties*.—White resin, sl. sol. water, imparting an acid reaction; v. sol. alcohol, insol. ether. It melts under hot water, and then has a silky appearance. Dissolves readily in alkalis and alkaline carbonates. Dextrorotatory,  $[\alpha]_D^{20}$ ; the sodium salt is optically inactive (Hoppe, C. G. 1859, 65). It differs from glycocholic acid by its sparing solubility in water, and by forming pps. insol. water with baryta and lime. A solution of its sodium salt is ppd. by metallic salts, even by  $NaOH$ ,  $KCl$ , and  $NH_4Cl$ . It gives Pettenkofer's test for bile.

*Reactions*.—1. Dilute sulphuric acid has no action; conc.  $H_2SO_4$  blackens it with evolution of  $SO_2$ .—2. Conc.  $HNO_3$  gives off nitrous fumes, and leaves a yellowish mass, chiefly consisting of oxalic acid and cholesteric acid  $C_{26}H_{44}O_6$ .—

3. Boiling conc.  $HCl$  aq. forms hyodyslysin and glycocholl. Boiling aqueous potash acts in like manner.

*Salts*.— $NH_4A'$ . Ppd. by adding ammonium chloride, carbonate, or sulphide, to fresh pigs' bile, or to a solution of the sodium salt. Crystalline powder; v. sol. water, v. sl. sol. conc. solutions of ammonium salts. Decomposed by boiling with water.— $NaA'$  aq.: white non-deliquescent powder. Its alcoholic solution yields, on evaporation, a transparent varnish. It has a persistent bitter taste.— $KA'$  aq.: white amorphous mass; ppd. by adding  $KCl$  to a solution of the  $Na$  salt. Melts under water or alcohol, but when quite dry it does not melt, even at  $120^\circ$ .— $BaA'$  2aq.: sl. sol. water, v. sol. alcohol.— $CaA'$  2aq.— $AgA'$ : gelatinous pp. which becomes flocculent on boiling.

( $\beta$ )-Hyoglycocholic acid  $C_{12}H_{21}NO_6$ ? Remains in the mother-liquor when the ordinary or ( $\alpha$ )-hyoglycocholate of sodium is ppd. by ice-cold saturated  $Na_2SO_4$  (Jolin, H. 11, 417; 12, 512; 13, 205). When this mother-liquor is evaporated sodium  $\beta$ -hyoglycocholate separates in dark brown oily drops, which solidify to a sticky mass. This is washed with ether, and then presents a white curdy appearance. It is v. sol. alcohol and water. The free acid and its salts greatly resemble their ( $\alpha$ )-isomerides, but the salts of the ( $\beta$ )-acid melt, as a rule, more easily, and have a less bitter taste. ( $\beta$ )-hyoglycocholic acid gives Pettenkofer's reaction. The ( $\alpha$ )-acid is ppd. by dilute acids more readily than the ( $\beta$ )-acid. The alkaline salts of the ( $\beta$ )-acid are more soluble in water than those of the ( $\alpha$ )-acid. The  $Ba$ ,  $Ca$ , and  $Mg$  salts of the ( $\beta$ )-acid differ from those of the ( $\alpha$ )-acid in dissolving in excess of the sodium salt. The sodium salt of the ( $\beta$ )-acid is dextrorotatory.

**HYOSCINE**. This name was first used to denote the base, subsequently proved to be tropine, obtained by saponifying hyoscyamine. It was then given to a base that accompanies hyoscyamine (q. v.).

**HYOSCINIC ACID** is identical with **TROPIC ACID**.

**HYOSCYAMINE**  $C_{17}H_{27}NO_3$ . *Duboisine*. *Daturine*. [109°]. An isomeride of atropine occurring in henbane (*Hyoscyamus niger*) and in other species of *Hyoscyamus* (Geiger a. Hesse, A. 7, 270; Höhn a. Reichardt, A. 157, 98). It occurs both in the seeds and in the juice of these plants, and is accompanied by hyoscyne (Ladenburg, A. 206, 282). It accompanies atropine in the seeds of the deadly nightshade (*Atropa Belladonna*); indeed Ladenburg (B. 21, 3065) is of opinion that atropine is an optically inactive base standing to hyoscyamine in the relation of racemic acid to levotartaric acid. From 20 g. of commercially pure atropine atropinechloride Ladenburg isolated by recrystallisation 1 g. of hyoscyamine atropinechloride, and to this he attributes the statement that atropine can be converted into hyoscyamine. Hyoscyamine occurs, mixed with atropine, in the seeds of *Datura Stramonium* (Pesci, G. 12, 89; Ladenburg, C. R. 90, 874; E. Schmidt, A. 208, 196), and in the leaves and twigs of *Duboisia myoporioides* (F. v. Müller a. Rummel, C. J. 85, 32; Gerrard, Ph. [8] 8, 187; Ladenburg a. Petersen, B. 20, 1601). Hyoscyamine mixed with hyoscyne occurs in the root

of *Scopolia japonica*; hyoscyamine also occurs in the root of *Scopolia Hladnackiana* (E. Schmidt & Henschoke, *Ar. Ph.* [3] 28, 185, 214).

**Preparation.**—Henbane seeds are extracted with boiling alcohol (90 p.c.) acidulated with tartaric acid, and when the alcohol is distilled off the residue separates into two layers. The upper layer is a green oil, which is shaken with dilute  $H_2SO_4$ , and the acid liquid, after nearly neutralising with  $K_2CO_3$ , is filtered and evaporated to a syrup. When alcohol is added to this syrup  $K_2SO_4$  separates, and the alcoholic solution must be freed from alcohol by distillation, mixed with a little water, and shaken with  $K_2CO_3$  and chloroform. The alkaloid is extracted from the chloroform by dilute  $H_2SO_4$ , and the acid solution, decolourised by animal charcoal, evaporated, and allowed to stand in contact with  $CaCO_3$ . The liquid is finally mixed with sand, evaporated over  $H_2SO_4$ , and the alkaloid extracted by chloroform, from which it crystallises in long prisms (Duquesnel, *J. Ph.* [5] 5, 181).

**Properties.**—Needles (from dilute alcohol), or prisms (from  $CHCl_3$ ). More soluble in water and dilute alcohol than atropine. Levorotatory:  $[\alpha]_D = -21^\circ$ . It enlarges the pupil of the eye in the same way as atropine. It will not sublime (Blyth).

**Reactions.**—1. Converted into atropine by heating for 5 or 6 hours above its melting-point (E. Schmidt, *B. 21*, 1829). The optical activity of hyoscyamine may likewise be diminished by allowing its alcoholic solution to stand in the cold after a slight addition of one of the following bases:  $NaOH$ ,  $KOH$ ,  $NH_3$ ,  $NMe_3$ , and  $NMe_4OH$  (Will, *B. 21*, 1717; Will & Bredig, *B. 21*, 2777). The optical activity cannot be reduced below  $[\alpha]_D = -1.89^\circ$  by this method, so that if Ladenburg is correct in holding atropine to be optically inactive, the conversion of hyoscyamine into atropine is incomplete.—2. Split up by boiling dilute  $HCl$  into the same products as atropine, viz.: tropine and tropic acid (Ladenburg, *B. 18*, 607). Baryta-water gives the same products.

**Salts.**— $B'HuCl$ :  $[159^\circ]$  (L);  $[162^\circ]$  (Nifl); golden leaflets with brilliant lustre (Ladenburg, *B. 18*, 109). The corresponding perchloride of atropine melts at  $197^\circ$  and has a lustre. The atropine aurochloride melts under water, that of hyoscyamine does not. Hyoscyamine aurochloride is less soluble in water at  $60^\circ$  than atropine aurochloride.— $B'H_2SO_4$  (dried at  $100^\circ$ ). Slender needles.  $206^\circ$ .—Oadmioiodide: needles (from alcohol); almost insol. in water.—Hydrobromide: compact prisms (from water).—Picrate: yellow dly pp. quickly changing to rectangular plates.—Platinophloride: triclinic (Fock, *B. 21*, 1730).

**Hyoscyne**  $C_8H_{11}NO_3$ . *Amorphous hyoscyamine*. Colourless syrupy fluid. Occurs in the mother-liquor from which hyoscyamine has crystallised. It closely resembles hyoscyamine, both in its mydriatic action on the pupil of the eye and in other respects. Boiled with water it splits up into tropic acid and pseudotropine. Solution of hyoscyne hydrochloride is precipitated by  $HgCl_2$ ,  $HgK_2I_2$ , and  $K_2FeO_4$ .

**Salts.**— $B'HuCl$ :  $[198^\circ]$ ; yellow prisms.

— $B'HI$ : aq. (dried at  $100^\circ$ ); small monoclinic prisms;  $a:b:c = .938:1:1.857$ . M. sol. water.— $B'HBrs$ : aq. trimetric prisms;  $a:b:c = .601:1:1.411$ . M. sol. water.— $B'H_2PtCl_6$ : octahedral crystals, sol. water and ether-alcohol.—Picrate  $B'OC_6H_4(NO_2)_2OH$ : prisms (Ladenburg, *B. 13*, 1549; 14, 1870).

**HYOTAUROCHOLIC ACID**  $C_{12}H_{19}NSO_4$  (?). Occurs in very small quantity in pigs' bile (Strecker, *A. 70*, 180). Apparently split up by boiling with  $HCl$  into taurine and hyocholic acid.

• **HYPO.** Use of this prefix applied to inorganic compounds: for hypo-compounds v. the element the hypo-compound of which is sought for, or the salts to the name of which hypo- is prefixed. Thus *hypo-bismuthic oxide* will be found under Bismuth, oxides or; *hypo-bromous acid* and *hypo-bromites* will be found under Bromine, oxy-acids or; *hypo-phosphites* will be found under Phosphorus, oxy-acids or.

**HYPOGÆIC ACID.** This name was given by Gossmann & Scheven (*A. 64*, 230) to an acid of the oleic series  $C_{18}H_{33}O_2$ , melting at  $33^\circ$ , supposed to exist in earth-nut oil (cf. Schröder, *A. 143*, 22; Caldwell & Gossmann, *A. 99*, 310). According to Schön (*A. 244*, 253), however, no such acid can be obtained from the oil, which contains olein and not its lower homologue.

**HYPOQUEBRACHINE**  $C_{12}H_{19}NO_2$  [ $80^\circ$ ]. An alkaloid occurring in quebracho bark (Hesse, *A. 211*, 264). It is a strong base with bitter taste, v. sol. alcohol, ether, and chloroform. Forms yellow amorphous salts.— $B'H_2PtCl_6$  aq.

**HYPOXANTHINE**  $C_4H_5N_3O_3$ . *Sarcine*. *Sarkine*. S. 33 in the cold;  $\mp 28$  at  $100^\circ$ . S. (alcohol) 11 at  $78^\circ$ . Occurs in the spleen of men and oxen (Scherer, *A. 73*, 329), in the bone-marrow of men and calves (Heymann, *Pf. 6*, 194). Occurs also in the muscular tissue of horses, oxen, and hares (Strecker, *A. 108*, 137), and in the blood of corpses (Salomon, *H. 2*, 94). It is a product of the reduction of uric acid  $C_4H_4N_4O_3$  by sodium-amalgam (Strecker & Rheineck, *A. 151*, 121). It is formed from blood-fibrin by the action of pancreas-ferment, and in much smaller quantity by the simple decay of blood-fibrin (Krause & Salomon, *B. 11*, 574; 12, 95; 13, 1166); in both cases its formation may be due to the presence of nuclein in the blood-fibrin, since it is not formed from purified fibrin (Kossel, *H. 5*, 156; Chittenden, *J. Th.* 1879, 61). Formed, together with xanthine, leucine, tyrosine, guanine, and carnine, in the decomposition of the proteid constituents of yeast (Schützenberger, *Bl. [2]* 21, 204; Kossel, *H. 3*, 291). Hypoxanthine is also formed by the action of chlorine-water on caffeine  $C_8H_{10}N_4O_2$  (Weidel, *A. 158*, 362). Hypoxanthine accompanies caffeine and xanthine in tea (Baginsky, *H. 8*, 896).

**Preparation.**—Extract of meat is dissolved in water and ppd. with lead subacetate. The filtrate is freed from lead by  $H_2S$  concentrated, and ppd. with ammonia and  $AgNO_3$ . The pp. is dissolved in the smallest possible quantity of dilute  $HCl$  (S.G. 1.1). The compound of hypoxanthine and  $AgNO_3$  separates on cooling, and is subsequently decomposed by  $H_2S$  (Neubauer, *Pf. 6*, 41).

**Properties.**—Minute crystals, al. sol. water, v. sl. sol. alcohol. Readily soluble in acids and

## HYPOXANTHINE

alkalis. Ppd. by  $\text{CO}_2$  from its solution in aqueous KOH. Neutral to litmus. Ppd. by phosphomolybdic acid in acid solution. According to Kossel (H. 4, 426) it cannot be oxidised to xanthine as formerly supposed.

Salts.— $\text{C}_5\text{H}_4\text{N}_2\text{O}_4\text{HCl}$  aq. tables.—  
 $(\text{C}_5\text{H}_4\text{N}_2\text{O}_4)_2\text{H}_2\text{PbCl}_2$ : yellow crystals, al. sol. cold, very soluble in hot water.— $\text{C}_5\text{H}_4\text{N}_2\text{O}_4\text{HBr}$ .—  
 $\text{C}_5\text{H}_4\text{N}_2\text{O}_4\text{HNO}_3$ : (at  $100^\circ$ ): large crystals.—

$\text{C}_5\text{H}_4\text{N}_2\text{O}_4\text{BaO}_2\text{H}_2$ : crystals.— $\text{C}_5\text{H}_4\text{N}_2\text{O}_4$  144: gelatinous pp.— $\text{C}_5\text{H}_4\text{N}_2\text{O}_4\text{AgNO}_3$ : flocculent pp. Crystallises from boiling  $\text{HNO}_3$  in small scales. Dissolves in 4,960 pts. of cold dilute  $\text{HNO}_3$  (S.G. 1.1). The ppn. of hypoxanthine by  $\text{AgNO}_3$  is prevented by the presence of gelatin in the solution (Salkowski, *Fy.* 6, 91).

**HYSTACRINE** v. DI-oxi-ANTHRAQUINONE.

## I

**IBOTIN**. A glucoside said to occur in the aqueous extract of the seeds of *Ligustrum Ibofa* (Martin, *Ar. Pa.* [8] 13, 338). The solution is ppd. with lead acetate, and the pp. decomposed by  $\text{H}_2\text{S}$  and exhausted with alcohol. It is a yellowish-white powder. Conc.  $\text{H}_2\text{SO}_4$  dissolves it, forming a red solution, which loses its colour on addition of water.

**ICACIN**  $\text{C}_{10}\text{H}_{16}\text{O}$  or  $(\text{C}_6\text{H}_5)_2\text{H}_2\text{O}$  (Flückiger);  $\text{C}_{10}\text{H}_{16}\text{O}$  (Stenhouse a. Groves, *A.* 180, 255; *C. J.* 29, 175);  $\text{C}_{10}\text{H}_{16}(\text{OH})$  (Hesse, *A.* 192, 181). The last formula represents it as amyrin in which one hydroxyl has been displaced by hydrogen. Icacin is the crystalline resin of conima or Incense resin (Soribe, *A. Ch.* [3] 13, 166). Steam-distillation expels an essential oil, conimene (q. v.), the remaining resin being almost entirely soluble in alcohol, from which it is deposited in silky needles on cooling. It may be purified by recrystallisation from ligroin. It crystallises in needles ( $175^\circ$ ). Insol. water, m. sol. boiling alcohol and petroleum, v. sol. ether,  $\text{CS}_2$ , and hot benzene. Hot conc.  $\text{H}_2\text{SO}_4$  blackens it.

**n-ICOSANE**  $\text{C}_{20}\text{H}_{42}$  ( $36^\circ$ ) ( $205^\circ$  at 15 mm.). S.G.  $d_4^{20}$  778;  $d_4^{25}$  749;  $d_4^{30}$  736. Formed by reduction of the dichloride of heptyl tridecyl ketone with HI and P. Product by treating n-decyl iodide with slices of sodium; the reaction which begins in the cold is finished by heating to  $150^\circ$ , and the product is mixed with alcohol, water being added, and the hydrocarbon rectified and finally crystallised from ether-alcohol. Obtained also by fractionating paraffin from brown coal (Kraff, *B.* 15, 1717; 19, 2220; 21, 2262).

**IOOOLINENE**  $\text{C}_{20}\text{H}_{42}$  *Eicosylene*. ( $315^\circ$ ). S.G.  $d_4^{25}$  818. Prepared from ozokerit, or the solid paraffin ( $37^\circ$ ) from brown coal by heating with  $\text{PbCl}_2$  at  $170^\circ$  and distilling the resulting  $\text{C}_{20}\text{H}_{42}\text{Cl}_2$  (Lippmann a. Hawliczek, *B.* 12, 69). Combines with Br and Cl forming oily  $\text{C}_{20}\text{H}_{42}\text{Br}_2$  and  $\text{C}_{20}\text{H}_{42}\text{Cl}_2$  (v. Di-chloro- and Di-bromo-icosane).

**IOOOLINENE**  $\text{C}_{20}\text{H}_{42}$  *Didecene*. ( $330^\circ$ – $335^\circ$ ). E.G.  $d_4^{25}$  936. [ $\eta$ ] $_D$  =  $-2^\circ$ . Obtained from the fraction ( $330^\circ$ – $340^\circ$ ) of the product of the distillation of colophony, by removing other unsaturated hydrocarbons by treatment with  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$  (Renard, *U. B.* 106, 1086). Colourless, non-fluorescent, oil. Does not alter when exposed to air, and is not affected by

cold. Occurs to the extent of 10 p.c. in the resin oil.

**IDRIALIN**  $\text{C}_{20}\text{H}_{38}\text{O}_2$ . The essential constituent of idrialite, a mineral found mixed with cinnabar in the mercury mine of Idria (Dumas, *A.* 5, 16; Schrotter, *A.* 24, 336; Laurent, *A. Ch.* [2] 66, 143; Bodeker, *A.* 52, 100; Goldschmidt, *J.* 1879, 865; *B.* 11, 1579). Extracted by boiling idrialite with xylene. Glittering plates. May be distilled in a current of  $\text{CO}_2$ . Almost insol. alcohol and ether, v. sol. boiling oil of turpentine, v. e. sol.  $\text{CS}_2$ . Fuming  $\text{H}_2\text{SO}_4$  forms a sulphonic acid. It gives no acetyl derivative. Oxidised by chromic acid to palmitic and stearic acids and oxydrialin  $\text{C}_{20}\text{H}_{38}\text{O}_3$ , a red substance which forms a deep-violet solution in  $\text{H}_2\text{SO}_4$ . Oxydrialin may be reduced to idrialin by distillation with zinc-dust, but it gives stearic acid when distilled in a current of hydrogen.

Bromine-water converts idrialin into  $\text{C}_{20}\text{H}_{38}\text{Br}_2\text{O}_2$ . Br in HOAc forms  $\text{C}_{20}\text{H}_{38}\text{Br}_2\text{O}_2$ , a reddish-yellow powder, v. sol. hot chloroform and benzene. Boiling conc.  $\text{HNO}_3$  forms  $\text{C}_{20}\text{H}_{38}(\text{NO}_2)_2\text{O}_2$ . Fuming  $\text{HNO}_3$  produces  $\text{C}_{20}\text{H}_{38}(\text{NO}_2)_3\text{O}_2$ .

**IDRYL** is identical with FLUORANTHENE (q.v.).

**IGASURINE** is impure BRUCINE (Shenstone, *C. J.* 39, 457).

**ILICYL ALCOHOL**  $\text{C}_{20}\text{H}_{40}\text{O}$  (Personne, *C. R.* 98, 1585; *B.* [2] 42, 150);  $\text{C}_{20}\text{H}_{40}\text{O}$  (Divers a. Kawakita, *C. J.* 53, 274). ( $175^\circ$ ) (P.); ( $172^\circ$ ) (D. a. K.). (above  $350^\circ$ ). Birdlime, obtained by fermentation of the inner bark of the holly *Ilex Aquifolium*, is a greenish tenacious substance, which when dried at  $100^\circ$  and extracted by chloroform or ligroin leaves an ash mainly composed of calcium phosphate. The evaporated extract contains a compound ether, which may be saponified by alcoholic KOH. An elastic substance resembling caoutchouc separates, and when the liquid portion is poured into water a gelatinous pp. is obtained, which can be purified by repeated crystallisation from alcohol. Needles (from alcohol or by sublimation); insol. cold water, m. sol. alcohol, miscible with boiling light petroleum, ether, and chloroform. On heating with palmitic acid a substance resembling birdlime is formed.

*Acetyl derivative* ( $206^\circ$ ).

**ILIXANTHIN**  $\text{C}_{20}\text{H}_{38}\text{O}_2$ . ( $198^\circ$ ). Occurs in the leaves of the holly (*Ilex Aquifolium*). Obtained from the leaves gathered in August by

$\text{C}_8\text{H}_{17}\text{NS}$  i.e.  $\text{C}_8\text{H}_{15}\text{C}(\text{NH})\text{S.C}_2\text{H}_5$ . Formed by passing  $\text{HCl}$  into a mixture of isoamyl mercaptan

3. **IMIDO-DI-FORMIC ETHER**  $C_2H_4NO_4$ ,  $[\alpha]_D^{20} +14.5$  (neat),  $d_4^{20} 1.266$ ,  $n_D^{20} 1.415$ ,  $n_D^{25} 1.408$ ,  $n_D^{30} 1.402$ ,  $n_D^{35} 1.396$ ,  $n_D^{40} 1.390$ ,  $n_D^{45} 1.384$ ,  $n_D^{50} 1.378$ ,  $n_D^{55} 1.372$ ,  $n_D^{60} 1.366$ ,  $n_D^{65} 1.360$ ,  $n_D^{70} 1.354$ ,  $n_D^{75} 1.348$ ,  $n_D^{80} 1.342$ ,  $n_D^{85} 1.336$ ,  $n_D^{90} 1.330$ ,  $n_D^{95} 1.324$ ,  $n_D^{100} 1.318$ ,  $n_D^{105} 1.312$ ,  $n_D^{110} 1.306$ ,  $n_D^{115} 1.300$ ,  $n_D^{120} 1.294$ ,  $n_D^{125} 1.288$ ,  $n_D^{130} 1.282$ ,  $n_D^{135} 1.276$ ,  $n_D^{140} 1.270$ ,  $n_D^{145} 1.264$ ,  $n_D^{150} 1.258$ ,  $n_D^{155} 1.252$ ,  $n_D^{160} 1.246$ ,  $n_D^{165} 1.240$ ,  $n_D^{170} 1.234$ ,  $n_D^{175} 1.228$ ,  $n_D^{180} 1.222$ ,  $n_D^{185} 1.216$ ,  $n_D^{190} 1.210$ ,  $n_D^{195} 1.204$ ,  $n_D^{200} 1.198$ ,  $n_D^{205} 1.192$ ,  $n_D^{210} 1.186$ ,  $n_D^{215} 1.180$ ,  $n_D^{220} 1.174$ ,  $n_D^{225} 1.168$ ,  $n_D^{230} 1.162$ ,  $n_D^{235} 1.156$ ,  $n_D^{240} 1.150$ ,  $n_D^{245} 1.144$ ,  $n_D^{250} 1.138$ ,  $n_D^{255} 1.132$ ,  $n_D^{260} 1.126$ ,  $n_D^{265} 1.120$ ,  $n_D^{270} 1.114$ ,  $n_D^{275} 1.108$ ,  $n_D^{280} 1.102$ ,  $n_D^{285} 1.096$ ,  $n_D^{290} 1.090$ ,  $n_D^{295} 1.084$ ,  $n_D^{300} 1.078$ ,  $n_D^{305} 1.072$ ,  $n_D^{310} 1.066$ ,  $n_D^{315} 1.060$ ,  $n_D^{320} 1.054$ ,  $n_D^{325} 1.048$ ,  $n_D^{330} 1.042$ ,  $n_D^{335} 1.036$ ,  $n_D^{340} 1.030$ ,  $n_D^{345} 1.024$ ,  $n_D^{350} 1.018$ ,  $n_D^{355} 1.012$ ,  $n_D^{360} 1.006$ ,  $n_D^{365} 1.000$ ,  $n_D^{370} 0.994$ ,  $n_D^{375} 0.988$ ,  $n_D^{380} 0.982$ ,  $n_D^{385} 0.976$ ,  $n_D^{390} 0.970$ ,  $n_D^{395} 0.964$ ,  $n_D^{400} 0.958$ ,  $n_D^{405} 0.952$ ,  $n_D^{410} 0.946$ ,  $n_D^{415} 0.940$ ,  $n_D^{420} 0.934$ ,  $n_D^{425} 0.928$ ,  $n_D^{430} 0.922$ ,  $n_D^{435} 0.916$ ,  $n_D^{440} 0.910$ ,  $n_D^{445} 0.904$ ,  $n_D^{450} 0.898$ ,  $n_D^{455} 0.892$ ,  $n_D^{460} 0.886$ ,  $n_D^{465} 0.880$ ,  $n_D^{470} 0.874$ ,  $n_D^{475} 0.868$ ,  $n_D^{480} 0.862$ ,  $n_D^{485} 0.856$ ,  $n_D^{490} 0.850$ ,  $n_D^{495} 0.844$ ,  $n_D^{500} 0.838$ ,  $n_D^{505} 0.832$ ,  $n_D^{510} 0.826$ ,  $n_D^{515} 0.820$ ,  $n_D^{520} 0.814$ ,  $n_D^{525} 0.808$ ,  $n_D^{530} 0.802$ ,  $n_D^{535} 0.796$ ,  $n_D^{540} 0.790$ ,  $n_D^{545} 0.784$ ,  $n_D^{550} 0.778$ ,  $n_D^{555} 0.772$ ,  $n_D^{560} 0.766$ ,  $n_D^{565} 0.760$ ,  $n_D^{570} 0.754$ ,  $n_D^{575} 0.748$ ,  $n_D^{580} 0.742$ ,  $n_D^{585} 0.736$ ,  $n_D^{590} 0.730$ ,  $n_D^{595} 0.724$ ,  $n_D^{600} 0.718$ ,  $n_D^{605} 0.712$ ,  $n_D^{610} 0.706$ ,  $n_D^{615} 0.700$ ,  $n_D^{620} 0.694$ ,  $n_D^{625} 0.688$ ,  $n_D^{630} 0.682$ ,  $n_D^{635} 0.676$ ,  $n_D^{640} 0.670$ ,  $n_D^{645} 0.664$ ,  $n_D^{650} 0.658$ ,  $n_D^{655} 0.652$ ,  $n_D^{660} 0.646$ ,  $n_D^{665} 0.640$ ,  $n_D^{670} 0.634$ ,  $n_D^{675} 0.628$ ,  $n_D^{680} 0.622$ ,  $n_D^{685} 0.616$ ,  $n_D^{690} 0.610$ ,  $n_D^{695} 0.604$ ,  $n_D^{700} 0.598$ ,  $n_D^{705} 0.592$ ,  $n_D^{710} 0.586$ ,  $n_D^{715} 0.580$ ,  $n_D^{720} 0.574$ ,  $n_D^{725} 0.568$ ,  $n_D^{730} 0.562$ ,  $n_D^{735} 0.556$ ,  $n_D^{740} 0.550$ ,  $n_D^{745} 0.544$ ,  $n_D^{750} 0.538$ ,  $n_D^{755} 0.532$ ,  $n_D^{760} 0.526$ ,  $n_D^{765} 0.520$ ,  $n_D^{770} 0.514$ ,  $n_D^{775} 0.508$ ,  $n_D^{780} 0.502$ ,  $n_D^{785} 0.496$ ,  $n_D^{790} 0.490$ ,  $n_D^{795} 0.484$ ,  $n_D^{800} 0.478$ ,  $n_D^{805} 0.472$ ,  $n_D^{810} 0.466$ ,  $n_D^{815} 0.460$ ,  $n_D^{820} 0.454$ ,  $n_D^{825} 0.448$ ,  $n_D^{830} 0.442$ ,  $n_D^{835} 0.436$ ,  $n_D^{840} 0.430$ ,  $n_D^{845} 0.424$ ,  $n_D^{850} 0.418$ ,  $n_D^{855} 0.412$ ,  $n_D^{860} 0.406$ ,  $n_D^{865} 0.400$ ,  $n_D^{870} 0.394$ ,  $n_D^{875} 0.388$ ,  $n_D^{880} 0.382$ ,  $n_D^{885} 0.376$ ,  $n_D^{890} 0.370$ ,  $n_D^{895} 0.364$ ,  $n_D^{900} 0.358$ ,  $n_D^{905} 0.352$ ,  $n_D^{910} 0.346$ ,  $n_D^{915} 0.340$ ,  $n_D^{920} 0.334$ ,  $n_D^{925} 0.328$ ,  $n_D^{930} 0.322$ ,  $n_D^{935} 0.316$ ,  $n_D^{940} 0.310$ ,  $n_D^{945} 0.304$ ,  $n_D^{950} 0.298$ ,  $n_D^{955} 0.292$ ,  $n_D^{960} 0.286$ ,  $n_D^{965} 0.280$ ,  $n_D^{970} 0.274$ ,  $n_D^{975} 0.268$ ,  $n_D^{980} 0.262$ ,  $n_D^{985} 0.256$ ,  $n_D^{990} 0.250$ ,  $n_D^{995} 0.244$ ,  $n_D^{1000} 0.238$ ,  $n_D^{1005} 0.232$ ,  $n_D^{1010} 0.226$ ,  $n_D^{1015} 0.220$ ,  $n_D^{1020} 0.214$ ,  $n_D^{1025} 0.208$ ,  $n_D^{1030} 0.202$ ,  $n_D^{1035} 0.196$ ,  $n_D^{1040} 0.190$ ,  $n_D^{1045} 0.184$ ,  $n_D^{1050} 0.178$ ,  $n_D^{1055} 0.172$ ,  $n_D^{1060} 0.166$ ,  $n_D^{1065} 0.160$ ,  $n_D^{1070} 0.154$ ,  $n_D^{1075} 0.148$ ,  $n_D^{1080} 0.142$ ,  $n_D^{1085} 0.136$ ,  $n_D^{1090} 0.130$ ,  $n_D^{1095} 0.124$ ,  $n_D^{1100} 0.118$ ,  $n_D^{1105} 0.112$ ,  $n_D^{1110} 0.106$ ,  $n_D^{1115} 0.100$ ,  $n_D^{1120} 0.094$ ,  $n_D^{1125} 0.088$ ,  $n_D^{1130} 0.08$

100, 1419; *Bz.* [7] 44, 96). Long prisms. Forms biuret when heated with aqueous  $\text{NH}_3$ .  $\text{AgC}_2\text{H}_3\text{NO}_2$ ; cubes, blackens at  $100^\circ$ .

#### $\beta$ -IMIDO-GLUTAMIC ETHER

$\text{CO}_2\text{Et} \cdot \text{CH}_2 \cdot \text{C}(\text{NH}) \cdot \text{CH}_2 \cdot \text{CONH}_2$ . [ $86^\circ$ ]. Formed by the action of aqueous ammonia on acetone-di-carboxylic ether  $\text{CO}(\text{OH}) \cdot \text{CO}_2\text{Et}$  (Stokes a. v. Pechmann, *Am.* 8, 377). Long, flat, colourless, flexible needles; sl. sol. cold water and ether; sol. hot water and alcohol; m. sol. hot  $\text{CHCl}_3$ . Heated above  $86^\circ$  gives off water and ammonia.  $\text{Fe}_2\text{Cl}_6$  gives deep red colouration. Soon decomposes in aqueous solution.  $\text{PtCl}_4$  gives  $(\text{NH}_4)_2\text{PtCl}_6$ .  $\text{NaNO}_2$  in acid solution gives a yellow pp. [ $178^\circ$ ]. Boiled with  $\text{Na}_2\text{CO}_3$  it gives di-oxy-amido-pyridine ( $\text{C}_5\text{H}_4\text{N}_2\text{O}_2$ ).

#### IMIDO-HEXOIC ACID. Nitrile

$\text{NH} \cdot \text{C}_6\text{H}_{11} \cdot \text{CN}$ . [ $48^\circ$ ]. (258). Formed by the action of Na on propionitrile dissolved in ether, the product being decomposed by water (Meyer, *J. pr.* [2] 38, 330). Plates, sl. sol. water, v. sol. alcohol and ether. Cold conc.  $\text{HClAq}$  converts it into  $\text{Et} \cdot \text{CO} \cdot \text{CHMe} \cdot \text{CN}$ . Conc.  $\text{HClAq}$  at  $150^\circ$  forms di-ethyl ketone,  $\text{NH}_3$ , and  $\text{CO}_2$ . Reduced by sodium in alcoholic solution to propylamine.

#### Imido-di-isohexoic acid. Nitrile

$\text{HN}(\text{C}_6\text{H}_{11}\text{CN})_2$ . Imidoisocapro-nitrile. Formed as a by-product of the action of urea upon valeric-aldehyde-cyanhydrin. The hydrochloride ( $\text{BHCl}$ ) forms white silky needles, [ $159^\circ$ ], v. sol. alcohol, insol. ether (Pinner a. Lifschütz, *B.* 20, 256; cf. Erlenmeyer, *B.* 14, 1868).

#### IMIDO-IMIDO-DIPHENYL SULPHIDE

$\text{C}_6\text{H}_5\text{N}_2\text{S}$  i.e.  $\text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{S} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}$ . Formed by treating imido-imido-diphenylsulphide hydrochloride with  $\text{FeCl}_3$  (Bernhsen, *A.* 230, 103). Brown needles (from dilute alcohol); v. sl. sol. water, m. sol. hot alcohol. Reduced by alcoholic ammonium sulphide to amido-imido-diphenyl sulphide. Its salts dye silk violet.— $\text{BHCl}$ : insol. ether, v. e. sol. water and alcohol.— $\text{B}'\text{H}_2\text{ZnCl}$ : long, dark-violet, needles; m. sol. water.

#### IMIDO-DI-MALONIC ACID. Amide

$\text{HN}(\text{CH}(\text{CO} \cdot \text{NH}_2))_2$ . Formed by heating chloro-malonic ether with alcoholic  $\text{NH}_3$  at  $140^\circ$  (Conrad a. Gutzeit, *B.* 15, 606). Prisms; sol. hot water.

#### IMIDO-METHYL ALCOHOL v. FORMIMIDO-METHYL

#### DI-IMIDO-NAPHTHOL v. AMIDO-NAPHTHOL-QUINONE-IMIDE.

#### IMIDO-DINAPHTHYL $\text{C}_{10}\text{H}_7\text{N}$ i.e.

$\text{C}_{10}\text{H}_7\text{NH}$ . Dinaphthylcarbasole. [ $216^\circ$ ]. Formed by boiling di-amido-dinaphthyl (dinaphthyl-ine) with an excess of  $\text{HCl}$  or other acid,  $\text{NH}_3$  being eliminated (Nietzke a. Goll, *B.* 18, 3259). Crystallises in long colourless needles or silvery plates. Sublimes in colourless needles. It dissolves in  $\text{H}_2\text{SO}_4$  with a reddish-brown colour, a trace of nitric acid added to this solution produces a dark-green colouration.

Picrate  $\text{B}'\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$ : [ $226^\circ$ ]; red needles (from benzene or alcohol); sublimable.

Acetyl derivative  $\text{C}_{10}\text{H}_7\text{N} \cdot \text{Ac}$ : [above  $300^\circ$ ]; colourless plates; sol. acetic acid and alcohol, insol. benzene.

Nitrosamine  $\text{C}_{10}\text{H}_7\text{N}(\text{NO})$ : [above  $300^\circ$ ]; small yellow plates; very sparingly sol. ordinary solvents.

#### Imido-( $\beta$ )-dinaphthyl $\text{NH} \cdot \text{C}_{10}\text{H}_7 \cdot \text{S}$ . [ $170^\circ$ ].

Obtained by heating ( $\beta$ )-imido-dinaphthyl sulphide with powdered copper in a current of  $\text{CO}$ , (Ris, *B.* 19, 2240). Almost colourless needles; sl. sol. alcohol, v. sol. ether, v. e. sol. benzene. Its solution shows intense bluish-violet fluorescence.

Picrate  $\text{B}'\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$ : [ $221^\circ$ ].

Acetyl derivative  $\text{C}_{10}\text{H}_7\text{N} \cdot \text{Ac}$ : [ $143^\circ$ ]. Long yellowish needles (from benzene); sl. sol. ether, and alcohol.

#### IMIDO-DI-NAPHTHYL OXIDE $\text{C}_{10}\text{H}_7\text{NO}$ i.e.

$\text{NH} \cdot \text{C}_{10}\text{H}_7 \cdot \text{O}$ . Oxy-di-naphthylamine. [ $301^\circ$ ].

Formed by heating imido-di-naphthyl sulphide with cupric oxide at  $270^\circ$ , and extracting with boiling benzene (Ris, *B.* 19, 2244). Lemon-yellow crystalline powder (from benzene). Cannot be distilled. Sl. sol. alcohol, ether, HOAc, and boiling benzene; v. sol.  $\text{H}_2\text{SO}_4$ .

Acetyl derivative  $\text{C}_{10}\text{H}_7\text{N} \cdot \text{Ac} \cdot \text{NO}$ . [ $235^\circ$ ].

Almost insol. alcohol and ligroin, m. sol. ether and benzene.

#### IMIDO-DI-NAPHTHYL SULPHIDE

$\text{C}_{10}\text{H}_7\text{NS}$  i.e.  $\text{NH} \cdot \text{C}_{10}\text{H}_7 \cdot \text{S}$ . Thiodinaphthyl

amine. [ $236^\circ$ ]. Formed by heating di-( $\alpha$ )-naphthylamide (10 pts.) with sulphur (2.4 pts. for 10 hours, the temperature being slowly raised to  $250^\circ$  (Ris, *B.* 19, 2241). The product is extracted with hot benzene, and boiled with copper powder. Pale yellowish-green needles. Sol. ether and HOAc, v. sol. boiling benzene. Conc.  $\text{H}_2\text{SO}_4$  forms a violet solution. Distillation over reduced copper forms imido-di-naphthyl. Distillation over  $\text{CuO}$  at  $270^\circ$  gives imido-dinaphthyl oxide.

Picrate  $\text{B}'(\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH})_2$ . [ $c.$   $256^\circ$ ]. Dark plates or yellow needles; almost insol. alcohol, ether, and benzene.

#### IMIDO-DI-OCTOIC ACID $\text{C}_{16}\text{H}_{31}\text{NO}$ i.e.

$\text{NH}(\text{CH}(\text{C}_6\text{H}_{13}) \cdot \text{CO})_2\text{H}$ . Imido-caprylic acid. [ $210^\circ$ – $415^\circ$ ]. Formed, together with formic acid  $\text{HCy}$ , and heptioic aldehyde, by boiling its nitrile (1 pt.) with  $\text{HClAq}$  (15 pts.) for an hour (Erlenmeyer a. Sigel, *A.* 177, 186). When the nitrile is heated with fuming  $\text{HClAq}$  at  $100^\circ$  it yields the acid and the imide, from which mixture the acid may be extracted by  $\text{Na}_2\text{CO}_3\text{Aq}$ . White tasteless powder, which becomes pasty at  $18^\circ$ . Almost insol. cold water and alcohol. Dissolves unaltered in boiling dilute (20 p.c.)  $\text{HCl}$ , brilliant needles of its hydrochloride separating again on cooling. Strong (40 p.c.)  $\text{HClAq}$  at  $180^\circ$  resolves it into amido-octoic acid and heptioic aldehyde.  $\text{CaMgA}$ : cryptocrystalline pp.

#### Imide $\text{C}_{16}\text{H}_{31}\text{N}_2\text{O}$ i.e.

$\text{NH} \cdot \text{CH}(\text{C}_6\text{H}_{13}) \cdot \text{CO} \cdot \text{NH} \cdot \text{CH}(\text{C}_6\text{H}_{13}) \cdot \text{CO}$ . [ $79$ – $5^\circ$ ]. Formed above. Needles, insol. cold, nearly insol. in water; v. sol. alcohol and ether.  $\text{B}'\text{H}$  minute needles, formed by passing  $\text{HCl}$  into ethereal solution. Boiling water splits it up into  $\text{HCl}$  and the imide. Boiling conc.  $\text{KOH}$  converts it into the acid.

Nitrile  $\text{C}_{16}\text{H}_{31}\text{N}$ . [ $c.$   $6^\circ$ ]. From heptioic aldehyde (ananthol) by combining it with  $\text{NH}_3$ .

and treating the resulting cananthol-ammonia with HCl. Dilute HCl then dissolves out the nitrile of amido-octoic acid, leaving the nitrile of imido-di-octoic acid undissolved. Thick oil; v. sol. alcohol and ether, v. sl. sol. water and dilute HCl aq. Split up by boiling with AgNO<sub>3</sub> giving heptico aldehyde and AgCy. B'HCl; crystals, sol. alcohol; decomposed by water into HCl and the nitrile.

## IMIDO-OKY. o. OXY-IMIDO.

## DI-IMIDO-DI-PHENYL-ACETYLENE (?)

$C_{14}H_{10}O_2$ ,  $s. c. \begin{smallmatrix} C_6H_5NH \\ C_6H_5 \end{smallmatrix} NH(?)$ . *Hydrazido-di-phenyl-acetylene*. *Di-imido-tolane*. [c. 880°]. Formed by treating an alcoholic solution of iso-di-nitro-benzil with tin and HCl (Göttsch, J.R. 16, 577). Thin tables. Sublimes at 250°. V. sl. sol. boiling alcohol, forming a solution exhibiting violet fluorescence. HNO<sub>3</sub> (S.G. 1.3) converts it into an amorphous indigo-blue compound. It does not combine with acids.

*Benzoyl derivative*  $C_{14}H_{12}Bz_2N_2O_2$ . [240°]. Pale yellowish needles (from toluene-alcohol), m. sol. boiling benzene, from which it crystallises as  $C_{14}H_{12}Bz_2N_2O_2C_6H_5$  on addition of a little alcohol.

## IMIDO-PHENYL-BENZGLYCOCYAMIDINE v. vol. i. p. 462.

IMIDO-PHENYL-PROPIONIC ACID  $C_6H_5.CH.CH.CO_2H$ . *Imido-cinnamic acid*.

$\begin{smallmatrix} NH \\ Ph.CH.CH.CO_2H \end{smallmatrix}$ . *Benzoyl derivative*  $C_{14}H_{11}NO_2$ , i.e.  $Ph.CH.CH.CO_2H$ . A body which probably has

$\begin{smallmatrix} NBz \\ Ph.CH.CH.CO_2H \end{smallmatrix}$  this constitution is obtained by saponification of its anhydride which is prepared by heating hippuric acid with benzoic aldehyde and acetic anhydride. The acid forms monoclinic needles. [225°]. Sol. alcohol and ether, nearly insol. water. Heated with aqueous HCl or NaOH it yields an acid  $C_{14}H_{11}O_3$  which is probably the *phenyl-glycidic acid*  $C_6H_5.CH.CH.CO_2H$ .

(Plöchl, B. 16, 2815).

*Benzoyl derivative of the anhydride*  $C_{14}H_{11}O_3$ . [165°]. Yellow needles, sol. hot alcohol, sl. sol. ether, insol. water. Formed as above.

## o-IMIDO-DI-PHENYL-DI-PROPIONITRILE

$C_{14}H_{11}N_4$ , i.e.  $(Ph.CH_2.CH(CN))_2NH$ . Formed together with o-amido-phenyl-propionitrile by the action of NH<sub>3</sub> on the compound of HCN and phenyl-acetic aldehyde (Erlenmeyer & Lipp, A. 219, 191). White crystalline powder [87°] or small needles (from water). Sol. alcohol or ether, insol. petroleum, v. sl. sol. water, m. sol. benzene. From ether it forms six-sided prisms [106°] or rhombic tables [109°], both belonging to the monoclinic system. They are perhaps polymerides.

Salt.—B'HCl: insol. ether.

IMIDO-DI-PHENYL-SULPHIDE  $C_{14}H_9NS$ 

i.e.  $NH \begin{smallmatrix} C_6H_5 \\ C_6H_5 \end{smallmatrix} S$ . *Thiodiphenylamine*. *Di-phenyl-thiasina*. [180°]. (c. 371° uncorr.); (390° at 40 mm.).

*Formation*.—1. By heating diphenylamine with sulphur or bodies that give off sulphur, such

as  $S_2Cl_2$  (Bernthsen, A. 280, 75).—2. By the action of  $S_2Cl_2$  on diphenylamine dissolved in benzene (Holzmann, B. 21, 2064).—3. In small quantity by heating o-amido-phenyl mercaptan with pyrocatechin for 30 hours at 230° (Bernthsen, B. 19, 3255).

*Preparation*.—By boiling diphenylamine (1,500 g.) with sulphur (580 g.) for 8 hours. The product is distilled in small portions (250 g.) and the distillate (60 g.) fractionated (Bernthsen, A. 230, 77; B. 16, 2897).

*Properties*.—Slightly yellowish plates (from alcohol or benzene). Sol. hot alcohol, HOAc, benzene and ether, sl. sol. ligroin. May be sublimed in plates. Has no basic properties, being insol. dilute HCl. It oxidises readily, the alcoholic solution turning red in air. FeCl<sub>3</sub> colours its alcoholic solution dark green. Bromine vapour does the same. The green colour is destroyed by alkalis. HNO<sub>3</sub> colours the solution in HOAc green. Cold conc. H<sub>2</sub>SO<sub>4</sub> gives off CO, and forms a greenish-brown solution which in thin layers appears rose-red. Hot conc. H<sub>2</sub>SO<sub>4</sub> forms a bluish-violet liquid. HNO<sub>3</sub> forms nitro-derivatives which are reduced by SnCl<sub>2</sub> to a leucobase, which on addition of FeCl<sub>3</sub> forms a violet dye. Cold alcoholic solutions of imido-diphenyl sulphide give: (a) with aqueous AgNO<sub>3</sub> a green colour and a black pp.; (b) with PtCl<sub>4</sub> a green pp.; (c) with CuSO<sub>4</sub>, HgCl<sub>2</sub>, and Pb(OAc)<sub>2</sub>, no pps.

*Reactions*.—1. Distillation over red-hot zinc dust gives some diphenylamine.—2. By boiling with copper powder it gives CuS and carbazole. 3. By heating with benzoic acid and ZnCl<sub>2</sub> there is formed phenyl-acridine.—4. EtBr gives ethyl-imido-di-phenyl sulphide  $NEt \begin{smallmatrix} C_6H_5 \\ C_6H_5 \end{smallmatrix} S$  [102°]

which crystallises in long thin white plates.—5. MeI forms the corresponding  $SC_6H_5.NMe$  [100°].

*Acetyl derivative*  $C_{14}H_9AcNS$ . [197°]. Prisms. V. sl. sol. hot HOAc, alcohol, and benzene. Its alcoholic solution is not turned green by FeCl<sub>3</sub>.

*Benzoyl derivative*  $C_{14}H_9BzNS$ . [171°]. Plates (from alcohol); p. sol. hot alcohol (Frankel, B. 18, 1844).

*Constitution*.—The imido group is shown by the ready formation of the acetyl and methyl derivatives. The sulphide character of the sulphur is shown by the oxidation of the methyl derivative to a sulphone. The amido-di-phenyl sulphide itself cannot be oxidised to a sulphone because the imidogen is first attacked. The body does not combine with MeI, but neither does Ph<sub>2</sub>S, although Me<sub>2</sub>S does. The S is not in p-position, because that is still unoccupied. Probably the formula is

which would also be indicated by its formation from o-amido-phenyl-mercaptan.

*References*.—AMIDO-, NITRO-, METAL-AMIDO-, and OXY-IMIDO-DIPHENYL SULPHIDES.

Imido-di-phenyl disulphide  $NH \begin{smallmatrix} C_6H_5 \\ C_6H_5 \end{smallmatrix} S_2$  [60°]. Formed by the action of  $S_2Cl_2$  on di-

# IMIDO-DI-PHENYL SULPHIDE.

nylamine dissolved in petroleum ether (Holtzmann, B. 21, 2063). Small yellow needles, sol. water, v. sl. sol. cold alcohol, ether, and benzene.

**α-IMIDO-DI-PROPIONIC ACID**  $C_6H_8N_2O_4$ , i.e.  $(CHMe.CO_2H)_2$ , 'Diethylidene-lactamic acid', 'lactamic acid'. Di-lactamic acid. Formed, ether with alanine, by treating aldehyde-ammonia with HCl and HCl successively (Hantz, A. 180, 34; 185, 44; 192, 375). The duct is boiled with lead hydrate, filtered, freed in lead by  $H_2S$ , concentrated, and mixed with phol. Alanine then separates, and the mother-liquor is mixed with  $ZnCO_3$  and evaporated to dryness. The residue of zinc imido-dipropionate is washed with water, and decomposed by  $HCl$ . Minute slender needles, v. sol. water, sl. alcohol.

**Salts.**— $NH_4HA$ : rectangular tables (from phol) or needles (from alcohol-ether). V. sol. in water, sl. sol. alcohol, insol. ether.— $ZnA$ : white dimetric tables, v. sl. sol. water, v. sol. in  $H_2O$ .— $CdA$ : minute needles (from water), sol. cold water, but can exist also in a less stable form.— $PbA$ : crystalline crusts (ppd. by adding alcohol to the aqueous solution).— $AgA$ : blue grains, v. sl. sol. water and alcohol.— $AgA$ : white pp.: explodes slightly on heating. May be crystallised from boiling water.— $HAHCl$ : extremely soluble crystals.

**Nitrosamine**  $NO.N(CHMe.CO_2H)_2$ . The diam salt of this acid is formed by treating acid, dissolved in  $HNO_3$ , with calcium nitrite, treating with lime, evaporating, and mixing with alcohol and ether. The free acid, obtained as this salt by treatment with oxalic acid, as flat colourless needles, v. sol. water and alcohol, sol. ether.

**Nitrile**  $C_6H_8N_4$ , i.e.  $NH(CMe.CN)_2$ , [68°]. An aldehyde-ammonia (1 mol.) is dissolved in 100 p.c.  $HCl$  (1 mol.), and HCl or  $H_2SO_4$  added to acid reaction, α-amido-propionitrile reacts as an oil. If, after removing this oil, mixture be allowed to stand for several days, flocs of imido-dipropionitrile separate; after a time these are followed by crystals of hyalinaline and finally of para-hydrocyanate (Erlenmeyer, A. 200, 190; cf. Urech, B. 6, 3). It is perhaps one of the products formed during a mixture of ammonia and alcohol over red-hot iron (Monari, C. R. 98, 105), colourless needles (from ether);  $a:b:c$  106:11:247;  $\beta = 70^\circ 21'$ ; m. sol. alcohol and water, sl. sol. water. Readily sublimable. When treated with dilute HCl it yields α-imido-dipropionic acid. With  $AgNO_3$  it gives on warming a  $AgO$ . Aqueous KOH has no action in cold, on warming it gives  $NH_3$  and aldehyde. It is a white crystalline powder, insol. ether, exposed by water into HCl and the free base. Nitrosamine  $NO.N(CHMe.CN)_2$ : yellow oil, heavier than water, sol. alcohol and ether.

**Imido-dipropionic acid**  $NH(CH_2.CO_2H)_2$ , mixed, together with β-amido-propionic acid, giving β-iodopropionic acid with  $NH_3$  (Hantz, 56, 40; cf. Mulder, B. 9, 1904, who could not isolate it). Syrup, which slowly crystallises.  $NH_4A$ : very slender tables.— $AgA$ : pp.— $AgNO_3$ : soluble crystals.

## DI-IMIDO-RESORCIN $C_6H_4(OH)_2$

Formed by oxidation of di-amido-resorcin with  $FeCl_3$ ,  $K_2Cr_2O_7$ , or exposure of the alkaline solution to the air (Tytke, B. 16, 556). Small spangles. Insol. water. Dissolves in aqueous HCl to a magenta-red solution, in strong  $H_2SO_4$  to a violet solution. By fin and HCl it is reduced again to di-amido-resorcin.

## DI-IMIDO-TEREPHTHALIC ACID. Tetra-hydride.

This acid is obtained by saponifying its ether with alcoholic KOH and ppg. with HOAc (Böninger, B. 21, 1765; cf. Baeyer, B. 19, 429). It crystallises in greenish-yellow crystals, almost insol. in ordinary solvents. It forms a colourless hydrochloride  $BH_2Cl$ , crystallising in plates. In its colourless derivatives the acid has become the desmotropic di-amido-terephthalic acid

## α-IMIDO-DI-m-TOLUIC ACID

[1:3]  $C_6H_3(CO_2H)_2.CH_2.NH.CH_2.C_6H_3(CO_2H)_2$  [1:3]. [above 800°]. Formed by reduction of the acid  $C_6H_3(CO_2H)_2.C(NH).S.C(NH).C_6H_3(CO_2H)_2$  (from m-cyano-benzoic acid and  $H_2S$ ) with zinc and HCl. Crystalline. V. sol. alcohol, ether, benzene, and  $CS_2$ ; sl. sol. hot water. Sublimable. Its characteristic zinc-salt is v. sol. water, alcohol, ether, benzene, and  $CS_2$  (Brömmes, B. 20, 529).

**IMIDO-DI-ISO-VALERONITRILE**  $C_8H_{10}N_4$ , i.e.  $NH(CHPr.CN)_2$ , [52°]. Formed, together with α-amido-isovaleronitrile and oxy-isovaleronitrile by treating isobutyric aldehyde-ammonia (25 g.) with (30 g. of) a 80 p.c. solution of HCl in the cold. The product is shaken with dilute (5 p.c.)  $HCl$  (200 g.) and ether. The ethereal solution is dried over calcium chloride, and saturated with HCl, whereupon the hydrochloride of imido-di-isovaleronitrile separates (Lipp, A. 205, 1; B. 13, 905). The hydrochloride is decomposed by  $NH_4OH$ , and the free nitrile extracted by ether, which leaves it on evaporation as an oil, slowly crystallising over  $H_2SO_4$ . Monoclinic prisms; v. sl. sol. water, v. sol. alcohol and ether.— $BHCl$ . Insol. water, which removes its HCl.

**IMINES.** Compounds of divalent hydrocarbon radicals with imidogen, e.g. ethylene-imine

## IMPERATORIN $C_{15}H_{10}O_4$ , i.e.

$CH_3.O.C_6H_3.O.C_6H_3.O.OH$ ? Peucedanin. [76°] (Heut). Occurs in the root of masterwort (*Imperatoria Ostruthium*), together with terpenes (176°–220°) (Wackenroder & Wagner, J. 1854, 638); and also in the root of *Peucedanum officinale* (Schlatter, A. 5, 301; Bothe, J. pr. 46, 571; Heut, A. 176, 71). May be extracted from the root of *Peucedanum* by 90 p.c. alcohol, and recrystallised from ether-ligroin. Small trimetric six-sided prisms. According to H. A. Weidel (A. 124, 609) it melts for the first time at 82°, and afterwards at 75°. Insol. water; v. sl. sol. cold, v. sol. hot, alcohol; sol. ether. Has no taste.  $HNO_3$  gives nitro-imperatorin, oxalic acid, and tri-nitro-resorcin. Decomposed by

heating with HClAq into MeCl and oroselon  $C_{12}H_{12}O_2$ . Boiling alcoholic KOH gives formic acid and oroselone.

Nitro-imperatorin, so-called,  $C_{12}H_{11}NO_2$ ? [above 100°]. Plates (from alcohol). Converted by heating in gaseous  $NH_3$  into  $C_{12}H_{12}N_2O_2$ , which crystallises from alcohol in trimetric prisms, reconverted by acids into 'nitro-imperatorin.'

IMPERIALINE  $C_{21}H_{21}NO_2$ ? [254°].  $[\alpha]_D^{20} = -35.4^\circ$  (in chloroform). Occurs in the bulbs of *Fritillaria imperialis*. Extracted from the bulbs by rubbing up with lime, drying at 100°, and exhausting with hot chloroform. The extract is shaken with water acidified with tartaric acid, the alkaloid ppd. from the concentrated aqueous solution by  $Na_2CO_3$ , washed, and re-crystallised from alcohol (Fragner, B. 21, 3284). The yield is 1 p.p. Short colourless needles, turning yellow at 240°. V. a. sol. chloroform; m. sol. hot alcohol; sl. sol. ether, benzene, light petroleum, and isamyl alcohol; v. sl. sol. water. Its solutions have a bitter taste, and are levorotatory. Solutions of its salts are ppd. by the usual reagents for alkaloids. Conc.  $H_2SO_4$  turns it pale-yellow. A mixture of the base with sugar is turned by  $H_2SO_4$  yellowish-green, pale-green, flesh-colour, cherry-red, and dark violet successively.  $H_2SO_4$  and  $KNO_3$  give an orange-yellow colour. A solution of the base in HClAq is fluorescent, and becomes brownish-green when warmed.— $B'HCl$ : large crystals (from alcohol: HCl); v. sol. water and alcohol.— $B'H.PtCl_2$ : yellowish-red crystals (from hot dilute HClAq).— $B'HAuCl_4$ : yellow crystals. The aurochloride and platinochloride are both ppd. in oily drops when ether is added to their hot alcoholic solutions, but after washing with ether they may be crystallised from hot dilute HCl. The sulphate is very hygroscopic. The oxalate crystallises only from very concentrated solutions.

INACTOSE. According to Maumené (Bl. [2] 82, 452; 43, 773) this inactive sugar may be formed by dissolving silver nitrate (20 g.) in a solution of cane-sugar (20 g.) in water (100 c.c.); after 24 hours the solution becomes dark-brown, and it is then heated to 100°, filtered, and evaporated on a water-bath. The residue is heated to 140°, dissolved in water, and filtered. To prep the solution from silver it is treated with a little  $CaCl_2$ , and filtered; the sugar is then ppd. by alcohol. Inactive syrup. Its solution readily dissolves lime.

INCENSE v. CONIMENE, ICACIN, and OLIRANUM.

INDAMINES. Colouring matters, the chromogen of which has the general formula  $R' \begin{smallmatrix} \diagup NH \\ \diagdown NH \end{smallmatrix} \diagdown$ , where  $R'$  is an aromatic nucleus, the nitrogen atoms occupying the *para*-position to one another, and  $R$  a hydrocarbon radicle (usually aromatic). The colouring matters themselves are derived by the introduction of a basylous or chlorous group into one of the hydrocarbon radicles (usually  $R'$ ). The indamines may therefore be represented as derived from the (unknown) di-imide of quinone  $C_6H_2 \begin{smallmatrix} \diagup NH \\ \diagdown NH \end{smallmatrix} \diagdown$ , which is probably the true chromogen. In the indamines proper the chromophor is amidogen or alkylated amidogen, the corresponding com-

pounds in which the chromophor is hydrazyl being termed *indophenols*.

Indamines are formed by the oxidation of a mixture of a *p*-diamine with an amine in which the position *para*- to an amidogen is occupied by hydrogen. Thus a mixture of tolylene-*p*-diamine and *o*-toluidine reacts thus:

(Nietzki, B. 10, 1157; Nietzki & Otto, B. 21, 1736). In this reaction we may suppose that the tolylene-*p*-diamine is first oxidised to tolu-

quinone di-imide  $C_6H_4Me \begin{smallmatrix} \diagup NH \\ \diagdown NH \end{smallmatrix} \diagdown$ , and that this unstable substance then reacts upon the *o*-toluidine.

The indamine hydrochloride

obtained by the oxidation of a mixture of *p*-phenylene-diamine with di-methyl-aniline is different from the indamine hydrochloride

$C_6H_4 \begin{smallmatrix} \diagup NMe_2Cl \\ \diagdown N.C_6H_4NH_2 \end{smallmatrix} \diagdown$  obtained by oxidising a mixture of di-methyl-*p*-phenylene diamine with aniline.

The red dye obtained by oxidising di-methyl-*p*-phenylene-diamine with bromine in HOAc (Wurster, B. 12, 2072) is also a derivative of

quinone di-imide:  $C_6H_4 \begin{smallmatrix} \diagup NH \\ \diagdown NMe_2Br \end{smallmatrix} \diagdown$ , and reacts with amines forming indamines, and with phenols forming indophenols.

Nitroso-di-methyl-aniline and quinone chlorimide also react with amines and phenols forming indamines and indophenols respectively; thus, nitroso-dimethylaniline hydrochloride acts upon *m*-tolylene diamine forming tolylene-blue (Witt, B. 12, 938):  $C_6H_4 \begin{smallmatrix} \diagup NO \\ \diagdown NMe_2HCl \end{smallmatrix} \diagdown + C_6H_4Me(NH_2)_2$

$= C_6H_4 \begin{smallmatrix} \diagup NMe_2Cl \\ \diagdown N.C_6H_4Me(NH_2)_2 \end{smallmatrix} \diagdown + H_2O$ , while with gallic acid it forms gallocyanine:

In the last reaction the hydrogen represented as liberated is in reality employed in reducing another portion of the nitroso-dimethyl-aniline (Nietzki & Otto, B. 21, 1740). The (β)-naphthol violet obtained by Meldola (C. J. 89, 87) by the action of nitroso-di-methyl-aniline upon (β)-naphthol may also be represented as an indophenol

$C_6H_4 \begin{smallmatrix} \diagup NMe_2Cl \\ \diagdown N.C_6H_4OH \end{smallmatrix} \diagdown$  or perhaps as containing two atoms of hydrogen less:  $C_6H_4 \begin{smallmatrix} \diagup NMe_2Cl \\ \diagdown N.C_6H_3 \end{smallmatrix} \diagdown$

A similar violet dye may be obtained by the

phenylamine dissolved in petroleum ether (Holtmann, B. 21, 2068). Small yellow needles, insol. water, v. sl. sol. cold alcohol, ether, and benzene.

**$\alpha$ -IMIDO-DI-PROPIONIC ACID**  $C_6H_{11}NO_4$ , i.e.  $NH(CHMe.CO_2H)_2$ , *Diethylidene-lactamic acid*, *Didenlactamic acid*, *Dilaclamic acid*. Formed, together with alanine, by treating aldehyde-ammonia with HCl and HCl successively (Heints, A. 160, 85; 165, 44; 202, 375). The product is boiled with lead hydrate, filtered, freed from lead by  $H_2S$ , concentrated, and mixed with alcohol. Alanine then separates, and the mother-liquor is mixed with  $ZnCO_3$  and evaporated to dryness. The residue of zinc imido-dipropionate is washed with water, and decomposed by  $H_2S$ . Minute slender needles, v. sol. water, insol. alcohol.

**Salts.**— $NH_4HA$ : rectangular tables (from alcohol) or needles (from alcohol-ether). V. sol. water, sl. sol. alcohol, insol. ether.— $ZnA$ : minute dimetric tables, v. sl. sol. water, v. sol. HClAq.— $CaA$ : minute needles (from water), v. sol. cold water, but can exist also in a less soluble form.— $PbA$ : crystalline crusts (ppd. by adding alcohol to the aqueous solution).— $CuA$ : blue grains, v. sl. sol. water and alcohol.— $AgA$ : white pp.; explodes slightly when heated. May be crystallised from boiling water.— $HA/HCl$ : extremely soluble crystals.

**Nitrosamine**  $NO.N(CHMe.CO_2H)_2$ . The calcium salt of this acid is formed by treating the acid, dissolved in  $HNO_3$ , with calcium nitrite, neutralising with lime, evaporating, and mixing with alcohol and ether. The free acid, obtained from this salt by treatment with oxalic acid, forms flat colourless needles, v. sol. water and alcohol, sol. ether.

**Nitrile**  $C_6H_9N$ , i.e.  $NH(CMe.CN)_2$ . [68°]. When aldehyde-ammonia (1 mol.) is dissolved in dilute (80 p.c.) HCl (1 mol.), and HCl or  $H_2SO_4$  is added to acid reaction,  $\alpha$ -imido-propionitrile separates as an oil. If, after removing this oil, the mixture be allowed to stand for several days, needles of imido-dipropionitrile separate; after some time these are followed by crystals of hydrocyanaldine and finally of para-hydrocyanaldine (Erlenmeyer, A. 200, 420; cf. Urech, B. 6, 1115). It is perhaps one of the products formed by passing a mixture of ammonia and alcohol-vapour over red-hot iron (Monari, C. R. 98, 105). Monoclinic needles (from ether);  $\alpha:b:d = 1.066:1.1:2.47$ ;  $\beta = 70^\circ 21'$ ; m. sol. alcohol and ether, sl. sol. water. Readily sublimates. When heated with dilute HCl it yields  $\alpha$ -imido-dipropionic acid. With  $AgNO_3$  it gives on warming a pp. of  $AgC_2H_4O_2$ . Aqueous KOH has no action in the cold, on warming it gives  $NH_3$  and aldehyde.  $BHCl$ : white crystalline powder, insol. ether, decomposed by water into HCl and the free nitrile. Nitrosamine  $NO.N(CHMe.CN)_2$ : pale yellow oil, heavier than water, sol. alcohol and ether.

**$\beta$ -Imido-dipropionic acid**  $NH(CH_2.CO_2H)_2$ . Obtained, together with  $\alpha$ -imido-dipropionic acid, by boiling  $\beta$ -iodopropionic acid with  $NH_3$  (Heints, A. 156, 40; cf. Mulder, B. 9, 1904, who could not obtain it). Syrup, which slowly crystallises.— $PbHA$ : very slender tables.— $AgA$ : pp.— $AgHA/AgNO_3$ : soluble crystals.

## DI-IMIDO-RESORCIN $C_6H_4(OH)_2$

Formed by oxidation of di-amido-resorcin with  $FeCl_3$ ,  $K_2Cr_2O_7$ , or exposure of the alkaline solution to the air (Type, B. 16, 558). Small spangles. Insol. water. Dissolves in aqueous HCl to a magenta-red solution, in strong  $H_2SO_4$  to a violet solution. By  $Sn$  and HCl it is reduced again to di-amido-resorcin.

## DI-IMIDO-TEREPTHALIC ACID. Tetra-

hydride.  $CH(C(NH).CH(CO_2H)_2)_2$ . This acid is obtained by saponifying its ether with alcoholic KOH and ppg. with HOAc (Böninger, B. 21, 1765; cf. Baeyer, B. 19, 429). It crystallises in greenish-yellow prisms, almost insol. ordinary solvents. It forms a colourless hydrochloride  $BH_2Cl$ , crystallising in plates. In its colourless derivatives the acid has become the desmotropic di-amido-terephthalic acid

$CH(C(NH_2).C(CO_2H)_2)_2$ . [1:3]  $C_6H_4(CO_2H).CH_2.NH.CH_2.C_6H_4(CO_2H)$  [1:3]. [above 300°]. Formed by reduction of the acid  $C_6H_4(CO_2H).C(NH).S.C(NH).C_6H_4(CO_2H)$  (from *m*-cyano-benzoic acid and  $H_2S$ ) with zinc and HCl. Crystalline. V. sol. alcohol, ether, benzene, and  $CS_2$ ; sl. sol. hot water. Sublimable. Its characteristic zinc-salt is v. sol. water, alcohol, ether, benzene, and  $CS_2$  (Brümme, B. 20, 529).

**IMIDO-DI-ISO-VALERONITRILE**  $C_8H_{11}N$ , i.e.  $NH(CHPr.CN)_2$ . [53°]. Formed, together with  $\alpha$ -imido-isovaleronitrile and oxy-isovaleronitrile by treating isobutyric aldehyde-ammonia (25 g.) with (30 g.) of a 80 p.c. solution of HCl in the cold. The product is shaken with dilute (5 p.c.) HClAq (200 g.) and ether. The ethereal solution is dried over calcium chloride, and saturated with HCl, whereupon the hydrochloride of imido-di-isovaleronitrile separates (Lipp, A. 205, 1; B. 18, 905). The hydrochloride is decomposed by  $NH_4OH$ , and the free nitrile extracted by ether, which leaves it on evaporation as an oil, slowly crystallising over  $H_2SO_4$ . Monoclinic prisms; v. sl. sol. water, v. sol. alcohol and ether.— $BHCl$ . Insol. water, which removes its HCl.

**IMINES.** Compounds of divalent hydrocarbon radicals with imidogen, e.g. *ethylene-imine*

$CH_2=CH-NH$

**IMPERATORIN**  $C_{15}H_{14}O$ , i.e.  $CH_3.O.C_6H_4.O.C_6H_4.O.CH_3$ . [76°] (Heut). Occurs in the root of masterwort (*Imperatoria Ostruthium*), together with terpenes (176°–220°) (Wackemöder & Wagner, J. 1854, 638); and also in the root of *Peucedanum officinale* (Schlatter, A. 5, 201; Bothe, J. pr. 46, 871; Heut, A. 176, 71). May be extracted from the root of *Peucedanum* by 90 p.c. alcohol, and recrystallised from ether-ligroin. Small trimetric six-sided prisms. According to Hillebrandt & Weidel (A. 124, 66) it melts for the first time at 82°, and afterwards at 75°. Insol. water; v. sl. sol. cold, v. sol. hot, alcohol; sol. ether. Has no taste.  $HNO_3$  gives nitro-imperatorin, oxalic acid, and tri-nitro-resorcin. Decomposed by

# NDAMINES.

heating with HClAq into MeCl and oroselon  $C_7H_3O_6$ . Boiling alcoholic KOH gives formic acid and oroselone.

Nitro-imperatorin, so-called  $C_{17}H_{11}NO_8$ ? [above 100°]. Notes (from alcohol). Converted by heating in gaseous  $NH_3$  into  $C_{17}H_{13}N_2O_8$ , which crystallises from alcohol in trimetric prisms, reconverted by acids into 'nitro-imperatorin'.

**IMPERIALINE**  $C_{17}H_{11}NO_8$ ? [254°].  $[\alpha]_D^{20} = -85.4^\circ$  (in chloroform). Occurs in the bulbs of *Fritillaria imperialis*. Extracted from the bulbs by rubbing up with lime, drying at 100°, and exhausting with hot chloroform. The extract is shaken with water acidified with tartaric acid, the alkaloid ppd. from the concentrated aqueous solution by  $Na_2CO_3$ , washed, and re-crystallised from alcohol (Fragner, B. 21, 3284). The yield is 1 p.c. Short colourless needles, turning yellow at 240°. V. e. sol. chloroform; m. sol. hot alcohol; al. sol. ether, benzene, light petroleum, and isomyl alcohol; v. sl. sol. water. Its solutions have a bitter taste, and are laevo-rotatory. Solutions of its salts are ppd. by the usual reagents for alkaloids. Conc.  $H_2SO_4$  turns it pale-yellow. A mixture of the base with sugar is turned by  $H_2SO_4$  yellowish-green, pale-green, flesh-colour, cherry-red, and dark violet successively.  $H_2SO_4$  and  $KNO_3$  give an orange-yellow colour. A solution of the base in HClAq is fluorescent, and becomes brownish-green when warmed.—BHCl: large crystals (from alcohol-HCl); v. sol. water and alcohol.—B $\cdot$ H $\cdot$ POCl: yellowish-red crystals (from hot dilute HClAq).—B $\cdot$ H $\cdot$ AuCl: yellow crystals. The aurochloride and platinumochloride are both ppd. in oily drops when ether is added to their hot alcoholic solutions, but after washing with ether they may be crystallised from hot dilute HCl. The sulphate is very hygroscopic. The oxalate crystallises only from very concentrated solutions.

**INACTOSE**. According to Mauméné (B. [2] 5, 652; 48, 773) this inactive sugar may be formed by dissolving silver nitrate (20 g.) in a solution of cane-sugar (20 g.) in water (100 c.c.); after 24 hours the solution becomes dark-brown, and it is then heated to 100°, filtered, and evaporated on a water-bath. The residue is heated to 140°, dissolved in water, and filtered. To free the solution from silver it is treated with a little  $CaCl_2$ , and filtered; the sugar is then ppd. by alcohol. Inactive syrup. Its solution readily dissolves lime.

**INCENSE** v. CONIMENE, ICACEN, and OLIMMUM.

**INDAMINES**. Colouring matters, the chromogen of which has the general formula  $\begin{matrix} & NH \\ & | \\ R' & -C- \\ & | \\ & NR' \end{matrix}$ , where R' is an aromatic nucleus, the nitrogen atoms occupying the para-position to one another, and R a hydrocarbon radicle usually aromatic). The colouring matters themselves are derived by the introduction of a phenyl or chlorophenyl group into one of the hydrocarbon radicles (usually B). The indamines may therefore be represented as derived from the (unknown) di-imide of quinone  $\begin{matrix} & NH \\ & | \\ C_6H_4 & -C-C- \\ & | \\ & NH \end{matrix}$ , which is probably the true chromogen. In the indamines proper the chromophor is amidogen or acylated amidogen, the corresponding com-

pounds in which the chromophor is hydroxyl being termed *indophenols*.

Indamines are formed by the oxidation of a mixture of a p-diamine with an amine in which the position para- to an amidogen is occupied by hydrogen. Thus a mixture of tolylene-p-diamine and o-toluidine reacts thus:

(Nietzki, B. 10, 1157; Nietzki a. Otto, B. 21, 1736). In this reaction we may suppose that the tolylene-p-diamine is first oxidised to tolu-

quinone diimide  $C_6H_4Me \begin{matrix} NH \\ | \\ C_6H_4Me \end{matrix}$ , and that this unstable substance then reacts upon the o-toluidine.

The indamine hydrochloride

obtained by the oxidation of a mixture of p-phenylene-diamine with di-methyl-aniline is different from the indamine hydrochloride  $C_6H_4 \begin{matrix} NMe_2Cl \\ | \\ N.C_6H_4NH_2 \end{matrix}$

obtained by oxidising a mixture of di-methyl-p-phenylene diamine with aniline.

The red dye obtained by oxidising di-methyl-p-phenylene-diamine with bromine in HOAc (Wurster, B. 12, 2072) is also a derivative of

quinone di-imide:  $C_6H_4 \begin{matrix} NH \\ | \\ NMe_2Br \end{matrix}$ , and reacts with amines forming indamines, and with phenols forming indophenols.

Nitroso-di-methyl-aniline and quinone chlor-imide also react with amines and phenols forming indamines and indophenols respectively; thus, nitroso-dimethylaniline hydrochloride acts upon m-tolylene diamine, forming tolylene-blue (Witt, B. 12, 933):  $C_6H_4 \begin{matrix} NO \\ | \\ NMe_2HCl \end{matrix} + C_6H_4Me(NH_2)_2$

$= C_6H_4 \begin{matrix} NMe_2Cl \\ | \\ N.C_6H_4Me(NH_2)_2 \end{matrix} + H_2O$ , while with gallic acid it forms gallocyanine:

In the last reaction the hydrogen represented as liberated is in reality employed in reducing another portion of the nitroso-dimethyl-aniline (Nietzki a. Otto, B. 21, 1740). The (8)-naphthol violet obtained by Meldola (C. J. 80, 87) by the action of nitroso-di-methyl-aniline upon (8)-naphthol may also be represented as an indophenol

$C_6H_4 \begin{matrix} NMe_2Cl \\ | \\ N.C_6H_4OH \end{matrix}$  or perhaps as containing

two atoms of hydrogen less:  $C_6H_4 \begin{matrix} NMe_2Cl \\ | \\ N.C_6H_3 \end{matrix}$

A similar violet dye may be obtained by the

# INDAMINES.

action of quinone di-chlorimide upon an alcoholic solution of ( $\beta$ )-naphthol:

*p*-Amido-phenyl-piperidine

$\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{N} \begin{array}{c} \text{CH}_2\text{CH}_2 \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{CH}_2\text{CH}_2 \end{array} \text{CH}_2$  reacts like *p*-amido-di-methyl-aniline in the formation of indamines (Lellmann a. Geller, *B.* 21, 2287). Thus, if to a cold neutral solution of *p*-amido-phenyl-piperidine hydrochloride and *m*-phenylene-diamine hydrochloride there be added the calculated quantity of a solution of  $\text{K}_2\text{Cr}_2\text{O}_7$ , there is formed a deep-blue solution, from which the colouring matter may be ppd. by zinc chloride as a brown powder.

The derivatives of imido-di-phenyl sulphide may be represented as indamines; thus, in

rial properties need not be connected with the presence of sulphur. The sulphur in Lauth's violet is represented by oxygen in gallocyanine and in ( $\beta$ )-naphthol violet.

**INDAZINE**  $\text{C}_8\text{H}_6\text{O}_2$ , i.e.  $\text{C}_6\text{H}_4 \begin{array}{c} \text{OH} \\ \diagup \quad \diagdown \\ \text{N} \\ \diagdown \quad \diagup \\ \text{NH} \end{array}$ .

*Indazole*. [146.5°]. (270°) at 743 mm. Formed by heating hydrazido-cinnamic acid, when it splits up into acetic acid and indazine

(Fischer a. Kuzel, *A.* 221, 280). Formed also by heating sulpho-*o*-hydrazido-cinnamic acid with conc.  $\text{HClAq}$  at 100° (Fischer a. Tafel, *A.* 227, 309). Slender needles. May be sublimed or distilled. Sl. sol. cold water or alkalis, v. sol. hot water, alcohol, and ether. Sol. dilute  $\text{HCl}$ . Gives off, when hot, an odour resembling resorcin.

With  $\text{HCl}$  and  $\text{NaNO}_2$  in the cold it forms yellow crystals of a nitroso-amine, which gives Liebermann's reaction. It does not reduce boiling Fehling's solution. It ppt. several metallic salts. Its hydrochloride separates from alcohol-ether in brownish crystals. Its sulphate forms colourless nodules. The picrate crystallises in yellow needles. Indazine is a much stronger base than indole  $\text{C}_6\text{H}_4 \begin{array}{c} \text{OH} \\ \diagup \quad \diagdown \\ \text{N} \\ \diagdown \quad \diagup \\ \text{CH}_3 \end{array}$ , and resists oxidation more powerfully.

**Nitrosamine**  $\text{C}_8\text{H}_6\text{N}_2\text{O}$ ,  $\begin{array}{c} \text{OH} \\ \diagup \quad \diagdown \\ \text{N} \cdot \text{NO} \end{array}$ . [74°].

Small yellow needles (from benzene).

**Bromo-indazine**  $\text{C}_8\text{H}_4\text{Br}_2\text{N}_2$ ,  $\begin{array}{c} \text{CH} \\ \diagup \quad \diagdown \\ \text{N} \cdot \text{NH} \end{array}$ . [124°].

Obtained by heating bromo-indazine carboxylic acid with a large quantity of water at 200°. Colourless needles, sl. sol. cold, m. sol. hot, water.

**Di-bromo-indazine**  $\text{C}_8\text{H}_2\text{Br}_4\text{N}_2$ . [240°]. Obtained by saturating the warm aqueous solution of bromo-indazine with bromine. Formed also by brominating indazine or indazine hydrochloride in aqueous solution, and by treating bromo-indazine carboxylic acid with bromine-water.

Colourless needles, v. sol. alcohol, ether, and hot aqueous  $\text{NaOH}$ . In alkaline solution it may be reduced to indazine by sodium-amalgam.

**Bromo-indazine-carboxylic acid**  $\text{C}_8\text{H}_4\text{Br}_2\text{N}_2\text{O}_2$ ,

$\begin{array}{c} \text{CO}_2\text{H} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagdown \quad \diagup \\ \text{N} \cdot \text{NH} \end{array}$  Formed by dissolving bromo-indazole-acetic acid in glacial  $\text{HOAc}$ , diluting somewhat, and boiling with gradual addition of chromic acid (Fischer a. Tafel, *A.* 227, 303). Small yellowish needles, v. sol. alkalis and alkaling carbonates, almost insol. water and  $\text{HClAq}$ .

**References.**—ETHYL-, METHYL-ETHYL-, and ETHYL-INDAZINE.

**Ethyl-indazine.** This term is given by Fischer and Tafel to  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CH}_2\text{CH}_3 \\ \diagup \quad \diagdown \\ \text{N} \cdot \text{NH} \end{array}$ , some of the alkyl derivatives of which have been prepared ( $\beta$ -ETHYL- $\psi$ -INDAZYL-ACETIC ACID,  $\beta$ -ETHYL- $\psi$ -INDAZINE, and METHYL-ETHYL- $\psi$ -INDAZINE).

**INDAZYL-ACETIC ACID**  $\text{C}_8\text{H}_7\text{N}_2\text{O}_2$ , i.e.  $\text{CH}_3\text{CO}_2\text{H}$

warming sodium-*o*-sulpho-di-*o*-cinnamic acid (which may be called di-*o*-cinnamic acid sodium sulphite)  $\text{C}_6\text{H}_4(\text{NH} \cdot \text{SO}_2\text{Na}) \cdot \text{CH} : \text{CH} \cdot \text{CO}_2\text{H}$  with  $\text{HCl}$  (Fischer a. Tafel, *A.* 227, 303). Prepared by dissolving *o*-hydrazido-cinnamic acid  $\text{C}_6\text{H}_4(\text{NH} \cdot \text{NH}_2) \cdot \text{CH} : \text{CH} \cdot \text{CO}_2\text{H}$  in alkalis, and shaking with air until it no longer reduces Fehling's solution. The acid is then ppd. by  $\text{HCl}$ .

**Properties.**—Slender, yellowish needles, v. e. sol. alcohol, acetic acid, acetone, and hot water, m. sol. ether; v. sl. sol. chloroform, benzene, and ligroin. Dissolves in alkalis and in mineral acids. On distillation it is split up into  $\text{CO}_2$  and methyl-indazine. It is completely decomposed by oxidising agents.

**Salt.**— $\text{CuA}$ , 2aq: pale green slimy pp., insol. hot water. Crystallises from hot alcohol in slender green needles.

Formed by adding a 4 p.c. solution of sodium nitrite to a very dilute solution of indazyl-acetic acid in aqueous  $\text{H}_2\text{SO}_4$  in the cold. Golden yellow needles. Insol. water and ligroin, v. e. sol. ether, chloroform, alcohol,  $\text{HOAc}$ , alkalis and warm  $\text{EtOAc}$ . Reduced by zinc-dust and  $\text{HOAc}$  to indazyl-acetic acid. It appears to exist in two modifications, one of which decomposes at 90° with evolution of gas, but without melting while the other, which is obtained by crystallisation from  $\text{HOAc}$ , melts at 128°.

**Bromo-indazyl-acetic acid**  $\text{C}_8\text{H}_4\text{Br}_2\text{N}_2\text{O}_2$ , i.e.  $\text{CH}_3\text{CO}_2\text{H}$

adding bromine-water to a solution of indazyl-acetic acid in dilute  $\text{HClAq}$ . Nearly colourless needles (from  $\text{HOAc}$ ), v. sol. alcohol and  $\text{HOAc}$  sl. sol. hot water.

**INDEXE**  $\psi$  INDOPHYRINE.

# **INDIGO**

**INDIGO** *Indigofera tinctoria*

**INDIGO** *Indigofera tinctoria*

**INDIGO** *Indigofera tinctoria*

**INDIGO** *Indigofera tinctoria*

**INDIGO**  $C_{16}H_{14}N_2O_2$ , probably

*Indigofera tinctoria*, L. 282, V.D. 9-10 (1906) (Sommaruga). A blue colouring matter occurring as a colorless glucoside (*Indican*) in various species of *Indigofera*, i.e. *Indigofera Anil*, *Indigofera tinctoria*, and in other plants, i.e. *Polygonum tinctorium*, *Isatis tinctoria*, &c. Commercial indigo, obtained from the juice of the *Indigofera* by fermentation, forms coppery blue lumps, and contains about 50 p.c. of pure indigo, together with indirubin, indirubin, indirubin, indirubin, &c.

**History.**—Indigo was probably one of the earliest known colouring matters, for its employment dates back to the most ancient times. The Egyptian mummy cases were certainly dyed with indigo, and it has been employed in India for many thousands of years (Gerardin, *Journ. de Chim. Med.* 1888, 224). It was well known to the Greeks and Romans, who imported it from India, and hence called it *indigo* or *indicum*. Pliny mentions it, and gives a test for its genuineness that it should burn with a purple flame when thrown on to glowing charcoal. In the Middle Ages indigo was used for dyeing and painting, but only to a small extent, and so little was known about it that it was generally believed to be a mineral. From the commencement of the sixteenth century the employment of indigo (from *Indigofera*) for dyeing began to rapidly increase. Prior to this time wood (*Isatis tinctoria*) was grown in great quantities in various parts of Europe, especially in Thüringen, and largely employed for blue dyeing (called Persian blue). The importation of indigo from India, which from the sixteenth century rapidly increased, in spite of much protective legislation soon replaced the wood indigo, until at the present time wood is only used as an adjunct to the indigo vat in order to start the fermentation. The present annual production of indigo is estimated as about 8,200 tons (value 4,000,000), of which 6,100 tons are produced in India, 1,100 tons in America, and 1,000 tons in China and other countries.

**Manufacture of commercial indigo.**—1. From *Indigofera*. As carried out in India the process is performed as follows: the cut plants are first steeped in water, where they ferment with evolution of  $CO_2$ ; the yellow liquor is then run off into another vat, where it is vigorously mixed with air by means of long stirrers. By this means the leucindigo (indigo-white) contained in the solution is oxidised, and the indigo separates out as a blue scum which finally settles to the bottom. The supernatant liquor is then run away, and the indigo is boiled with water for several hours, pressed, and dried. The formation of leucindigo from the glucoside indican, which is present in the plant, is effected by a special bacillus, which is strongly pathogenic and closely resembles the bacilli of pneumonia and rhinocleroma (E. Alvarez, *C. B.* 105, 286).

2. II.

2. From wood. The leaves are crushed, the mash is fermented, formed into balls, and dried.

**Preparation of pure indigo.**—1. From commercial indigo: (a) Finely powdered indigo (125 g.) and glucose (125 g.) are covered with hot 75 p.c. spirit in a flask of 6 litres capacity. After adding 100 c.c. of saturated alcoholic NaOH the flask is shaken with hot spirit and left to stand. The clear liquor is then decanted off and left exposed to the air, when the leucindigo (indigo-white) it contains is reoxidised to indigo-tint, which separates in small glistening needles. This is washed with alcohol, water, and finally with HCl, and is then sublimed under 80–40 mm. pressure (Fritzsche, *A.* 44, 290; Sommaruga, *A.* 195, 305).—(b) Boiling water (1½ pts.) is poured on a mixture of finely-powdered crude indigo (1 pt.) and slacked lime (2 pts.). Ferrous sulphate (1½ pts.) is then added, and the mixture is kept warm for several hours with exclusion of air. The alkaline solution of leucindigo is run into diluted HCl, by which it is precipitated, and by exposure to air is oxidised to indigo.—(c) In place of glucose or ferrous sulphate the reduction can be conveniently effected with alcohol and sodium stannite ( $SnCl_2$  and excess of NaOH) (Schunck, *Z.* 1865, 671).

2. Synthetically: (a) Together with indirubin by reduction of isatin chloride (from isatin and  $PCl_5$ ) with ammonium sulphide or with HI or zinc dust and acetic acid. The indirubin is removed by extraction with alcohol (Baeyer, *B.* 11, 1297; 12, 456).—(b) Cinnamic acid  $C_6H_5.CH=CH.CO_2H$  is converted into its ether by means of alcohol and sulphuric acid. This is nitrated at a low temperature with the theoretical quantity of  $HNO_3$  mixed with  $H_2SO_4$ . The product is a mixture of about equal quantities of o and p-nitro-cinnamic ethers  $C_6H_4(NO_2)CH=CH.CO_2Et$  from which the ortho-ether is separated by means of its greater solubility in alcohol. The ortho-ether is then converted into the acid by warming with conc.  $H_2SO_4$ , dried and converted into the dibromide  $C_6H_4(NO_2)CHBr.CHBr.CO_2H$  (1:2) by treatment with an equivalent quantity of bromine. By leaving the dibromide in contact with conc. NaOH the sodium salt of o-nitro-phenyl-propionic acid  $C_6H_4(NO_2)C_2H_4CO_2H$  is formed from which the free acid is precipitated by the addition of  $H_2SO_4$ , and is filtered off and washed. The o-nitro-phenyl-propionic acid (2 pts.) suspended in cold water (1 pt.) is neutralised with potassium carbonate (1 pt.), and then carefully mixed with potassium xanthate (3 pt.). On allowing the mixture to dry at the ordinary temperature indigo is slowly formed (Baeyer, *B.* 15, 2260; *E. P.* 1880, 1175; *C. C.* 1882, 366). The o-nitro-phenyl-propionic acid can also be converted into indigo by boiling its solution with glucose and sodium carbonate (Baeyer) or with glucose and potassium cyanide (Michael, *J. pr.* [2] 85, 254). (c) By adding NaOH (3 pts.) dissolved in cold water (180 pts.) to a solution of o-nitro-benzaldehyde (10 pts.) in acetone (15 pts.). The separation of the indigo is complete in two or three days. A better yield is obtained by previously preparing the aldehyde intermediate compound  $C_6H_4(NO_2)CH(OH)CH_2.CO_2H$  by slowly dropping a 1 p.c. solution of NaOH (about 5 pts.) into a cold solution of o-nitro-benzaldehyde (10 pts.) in pure acetone (14 pts.) diluted with 2 c.c.

# INDIGO.

equal volume of water. The NaOH solution is added until the mixture is slightly alkaline and a trace of indigo begins to be formed; the acetone is then distilled off and the condensation product is left. The latter is converted into indigo by dissolving it without purification in about 250 pts. of boiling water, cooling, and adding NaOH. The yield upon the *o*-nitro-benzaldehyde is 76 p.c. of the theoretical (Baeyer a. Drewsen, B. 15, 2856; Eng. Pat. 1889, 1266).

*Syntheses.*—1. By warming isatin

$\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{CO} \\ \diagup \end{smallmatrix} \text{C}(\text{OH})$  with  $\text{PCl}_5$ , phosphorus, and some acetyl chloride at  $70^\circ\text{--}80^\circ$  (Baeyer a. Emmerling, B. 8, 515). Isatin (*q. v.*) is formed synthetically by oxidation of amido-oxindole

$\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{CH}(\text{NH}_2) \\ \diagup \end{smallmatrix} \text{CO}$  (Baeyer, B. 11, 1228), by reduction of *o*-nitro-phenyl-glyoxylic acid from *o*-nitro-benzoic acid (Claisen a. Schrödl, B. 13, 360), or by boiling a solution of *o*-nitro-phenyl-propionic acid with alkalis (Baeyer, B. 15, 2259).

2. Together with indixin, by adding zinc dust or HI to an acetic acid solution of isatin chloride  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{CO} \\ \diagup \end{smallmatrix} \text{CCl}$ , formed from isatin and  $\text{PCl}_5$  (Baeyer, B. 11, 1297; 12, 457).

3. By the action of ammonium sulphide upon isatin chloride, upon  $\psi$ -isatoxim

$\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{CO} \\ \diagup \end{smallmatrix} \text{C}(\text{OH})$ , or upon isatin ethyl ether  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{CO} \\ \diagup \end{smallmatrix} \text{C}(\text{OEt})$  (Baeyer, B. 15, 2093; 16, 2203).

4. By the action of air or  $\text{FeCl}_3$  upon indoxyl  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{C}(\text{OH}) \\ \diagup \end{smallmatrix} \text{CH}_2$  or upon indoxyl-sulphuric acid  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{C}(\text{O}(\text{SO}_3\text{H})) \\ \diagup \end{smallmatrix} \text{CH}$  (Baumann a. Tiemann, B. 12, 1098).

5. In small quantity by oxidation of indole  $\text{C}_6\text{H}_7\text{N}$  with ozone (Nencki, B. 8, 727).

6. By the action of reducing agents such as glucose, lactose, sulphides or xanthates upon *o*-nitro-phenyl-propionic acid in alkaline solution, the yield being about 40 p.c. of the 'propionic acid':

$\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}_2\text{CO}_2\text{H} + 2\text{H}_2$   
 $\text{C}_6\text{H}_3\text{N}_2\text{O}_2 + 2\text{CO}_2 + 2\text{H}_2\text{O}$  (*v. supra*; Baeyer, B. 13, 2260).

7. In small quantity by heating *o*-nitro-phenyl-bxyacrylic acid  $\text{C}_6\text{H}_3(\text{NO}_2)\text{C}(\text{OH})\text{CH}=\text{CHCO}_2\text{H}$  by itself, or with phenol or acetic acid (Baeyer, B. 13, 2263).

8. Indoxyl  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{C}(\text{OH}) \\ \diagup \end{smallmatrix} \text{CH}_2$ , indoxylic acid  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{C}(\text{OH}) \\ \diagup \end{smallmatrix} \text{CO}_2\text{H}$ , or ethyl-indoxylic acid  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{C}(\text{OEt}) \\ \diagup \end{smallmatrix} \text{CO}_2\text{H}$  readily give indigo on oxidation with  $\text{FeCl}_3$ ,  $\text{CrO}_3$ , &c. or by atmospheric oxidation of the alkaline solutions. Indoxylic acid is obtained from its ethyl ether, which is formed by the action of alkaline reducing agents

upon isatogenic ether  $\text{C}_6\text{H}_3\text{N} \begin{smallmatrix} \text{O} \\ \diagup \end{smallmatrix} \text{C}(\text{CO}_2\text{Et})$ . Indoxyl is obtained by heating indoxylic acid (Baeyer, B. 14, 1742; German Patent 17,556).

9. By warming a mixture of indoxyl and glyoxylic acid with *o*-nitro-phenyl-propionic acid and  $\text{Na}_2\text{CO}_3$  (Baeyer, B. 14, 1745).

formed from the isomeric di-*o*-nitro-di-phenyl-di-acetylene  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{C}(\text{O})\text{C}(\text{O})\text{C}_6\text{H}_3(\text{NO}_2)_2$  by treatment with fuming  $\text{H}_2\text{SO}_4$ , is readily converted into indigo by reduction with ammonium sulphide, zinc dust and alkalis, glucose and alkalis, &c. With ammonium sulphide in the cold the reduction takes place quantitatively. The di-*o*-nitro-di-phenyl-di-acetylene is obtained by oxidation with potassium ferricyanide of the cuprous compound of *o*-nitro-phenyl-acetylene  $\text{C}_6\text{H}_3(\text{NO}_2)\text{C}(\text{OH})$  which is formed by boiling an aqueous solution of *o*-nitro-phenyl-propionic acid  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}_2\text{CO}_2\text{H}$  (Baeyer a. Landsberg, B. 15, 53; G. P. 19,366).

11. By the action of dilute alkalis upon a mixture of *o*-nitro-benzaldehyde  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CHO}$  with acetone, pyruvic acid, aldehyde, or acetophenone. Acetone and pyruvic acid give the best yields. In these reactions aldol-like condensation products are first formed and are converted into indigo by the further action of the alkali. Thus under the influence of a small quantity of alkali, *o*-nitrobenzaldehyde with acetone gives *o*-nitro- $\beta$ -phenyl- $\beta$ -oxy-ethyl-methyl ketone  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}(\text{OH})\text{CH}_2\text{COCH}_3$ ; whilst with aldehyde *o*-nitro-benzoaldehyde appears to form *o*-nitro- $\beta$ -phenyl- $\beta$ -oxy-pyruvic aldehyde  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}(\text{OH})\text{CH}_2\text{CHO}$ , with pyruvic acid *o*-nitro- $\beta$ -phenyl- $\beta$ -oxy-propionyl-formic acid  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}(\text{OH})\text{CH}_2\text{COCO}_2\text{H}$ . By treatment with a further quantity of an alkali all these condensation products yield indigo, whilst acetic, formic, or oxalic acid is split off, thus:  $2\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}(\text{OH})\text{CH}_2\text{COCH}_3 + 2\text{H}_2\text{O} = \text{C}_{12}\text{H}_7\text{N}_2\text{O}_2 + 2\text{CH}_3\text{CO}_2\text{H} + 2\text{H}_2\text{O}$  (Baeyer a. Drewsen, B. 15, 2856; E. P. 1882, 1266).

12. By the action of aqueous alkalis upon *o*-nitro-cinnamoyl-formic acid (*o*-nitro-styryl-glyoxylic acid)  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}=\text{CHCO}_2\text{H}$ , obtained by saturating a mixture of *o*-nitro-benzaldehyde and pyruvic acid with aqueous hydrochloric acid at  $10^\circ$ :  $2\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}=\text{CHCO}_2\text{H} = \text{C}_{12}\text{H}_7\text{N}_2\text{O}_2 + 2\text{CH}_3\text{CO}_2\text{H}$  (Baeyer a. Drewsen, B. 15, 2852).

13. *o*-Nitro-benzylidene-acetone  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}=\text{CHCOCH}_3$ , which is obtained by nitration of benzylidene-acetone, or by heating *o*-nitro- $\beta$ -phenyl- $\beta$ -oxy-ethyl methyl ketone  $\text{C}_6\text{H}_3(\text{NO}_2)\text{CH}(\text{OH})\text{CH}_2\text{COCH}_3$  with acetic anhydride, gives indigo by treatment with alcoholic KOH, precipitating with an acid, and then boiling with water or aqueous alkalis. The yield is small (Meister, Lucius, a. Brüning, E. P. 1882, 1453; Baeyer a. Drewsen, B. 15, 2855).

14. By heating the lactone of *o*-nitro- $\beta$ -phenyl- $\beta$ -oxy-propionic acid with water or acetic acid (Einhorn, B. 18, 2213).

15. By bromination or chlorination of acetyl-*o*-amido-acetophenone  $\text{C}_6\text{H}_3(\text{NHAc})\text{COCH}_3$ , or of acetyl-*o*-amido-phenyl-acetylene  $\text{C}_6\text{H}_3(\text{NHAc})\text{C}(\text{CH}_3)=\text{CH}_2$ , ac-bromo- and chloro-derivatives are obtained. These are converted by fuming  $\text{H}_2\text{SO}_4$  (10 to 20 pts.) into intermediate products, which give indigo on dissolving in aqueous alkalis and exposure to air. Indoxyl

probably an intermediate product in this reaction (Baeyer & Bloem, *B.* 17, 968; *German Patent* 21,382).

16. By the action of ammonium sulphide upon the *ortho-methoxy-ortho-chloro*- (or bromo-) nitroacetophenone (e.g.  $\text{C}_6\text{H}_4(\text{NO}_2)\text{CO}\cdot\text{CHCl}$ ), formed by chlorination or bromination of *ortho-nitroacetophenone* (Gevecke, *B.* 16, 2084; *A.* 221, 531; *J.* P. 23, 735).

17. By heating indoin  $\text{C}_{12}\text{H}_9\text{NO}_2$ .

**Formation.**—In addition to the above synthetic methods indigo is produced: 1. From its glucoside indican by the action of acids and air, or  $\text{FeCl}_3$ , or by fermentation under the influence of a special microbe (Schunck, *J.* 1855, 660; 857, 664; 1858, 465; *C. N.* 87, 223; 89, 129; Schunck & Römer, *B.* 10, 2311).—2. The potassium salt of indoxyl sulphuric acid, incorrectly called 'Indican,' is a normal constituent of the urine of animals, being formed in the organism by the oxidation of indole  $\text{C}_8\text{H}_7\text{NH}\text{CH}$ ,

which is a decomposition product of proteids. Indoxyl-sulphuric acid is readily oxidised to indigo by  $\text{FeCl}_3$ , &c., and under certain conditions is converted into indigo in the urine (Schunck & Hoppe-Seyler, *Arch. Pathol. Anat.* 17, 384; Baumann, *Pf.* 18, 291; Baumann & Rieger, *H.* 3, 254; Jaffe, *Pf.* 3, 448; Baumann & Tiemann, *B.* 12, 1098, 1192; 13, 408; Michailow, *B.* 20, 605; *J. R.* 1887, 326; Weber, *B.* 19, 171; Baeyer, *B.* 12, 1800).—3. By oxidation of encindigo (indigo-white) by air, &c. This reaction performed upon the fibre forms the usual method of dyeing indigo.

**Properties.**—Pure indigo begins to sublime at  $170^\circ$  (Schunck, *C. J.* 37, 617), forming a purple-red vapour and condensing to dichroic plates belonging to the rhombic system,  $a:b:c = 7.883:1:7.265$ ,  $\alpha = 78^\circ 30'$ ,  $\beta = 108^\circ$ . Under 50–80 mm. pressure it sublimes without any decomposition, and the vapour density has been taken under these conditions by Sommaruga (*A.* 195, 312), and found to correspond to the formula  $\text{C}_{16}\text{H}_8\text{N}_2\text{O}_2$ . Insol. water, alcohol, ether; dilute acids, or alkalis. *V. al. sol.* hot alcohol, amyl alcohol, acetone, or turpentine. *Sl. sol.* chloroform or acetic acid. *V. sol.* hot aniline, nitrobenzene, or phenol; from the latter solvents it crystallises on cooling (Stokvis, *J.* 1858, 789; Wartha, *B.* 4, 534; Jacobsen & Mehu, *J.* 1872, 682). *Sol. conc. H\_2SO\_4* without alteration to a yellowish-green solution, which exhibits a characteristic absorption spectrum between the D and d lines (Vogel, *B.* 11, 1364). The  $\text{H}_2\text{SO}_4$  solution by long standing or on warming becomes blue from formation of indigo-sulphonic acids.

**Reactions.**—1. Distilled with KOH it yields aniline (Fritzsche, *A.* 39776).

2. It dissolves in boiling aqueous KOH (S.G. 1445) to a yellow solution of isatinic acid and leucindigo (indigo-white):  $8\text{C}_{16}\text{H}_8\text{N}_2\text{O}_2 + 4\text{H}_2\text{O} = 2\text{C}_{16}\text{H}_9\text{NO}_2 + 3\text{C}_{16}\text{H}_9\text{N}_2\text{O}_2$ .

3. By fusion with KOH anthranilic acid  $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO}_2\text{H}$  [1.2] is formed (Böttlinger, *B.* 10, 369); by heating with KOH at  $300^\circ$  Cabours (*A. Ch.* [3] 13, 113) obtained salicylic acid.

4. By boiling with KOH and  $\text{MnO}_2$  it yields anthranilic and formic acids (Böttlinger).

5. Oxidising agents, such as chlorine, oxides

of chlorine,  $\text{HNO}_3$ , ferric salts, &c., convert it into isatin  $\text{C}_8\text{H}_5\text{NH}\text{CH}$ .

6. By damp chlorine it is converted into chlorisatin, dichlorisatin, trichlorisatin, and trichlorophenol. Bromine acts in the same way (Erdmann, *J. pr.* 19, 830).

7. With  $\text{HNO}_3$  it yields in succession isatin, nitrosalicylic acid, and finally picric acid.

8. Alkaline reducing agents, such as  $\text{FeSO}_4$  and NaOH, glucose and NaOH,  $\text{SnCl}_4$  and NaOH, convert it into leucindigo (indigo-white)  $\text{C}_{16}\text{H}_{11}\text{N}_2\text{O}_2$ .

9. By heating with aqueous sodium hydro-sulphite  $\text{Na}_2\text{SO}_3$  and excess of NaOH at  $180^\circ$ , indoline  $\text{C}_8\text{H}_9\text{NH}\text{CH}$  is formed (Glraud, *B.* 12, 2155). This body is also obtained by heating leucindigo (indigo-white) with zinc-dust and aqueous barium hydrate at  $180^\circ$ .

10. By heating with an excess of saturated  $\text{HI}$ , hydrocarbons and  $\text{NH}_3$  are produced (Berthelot, *Bl.* [2] 9, 189).

11. Unaltered by long boiling with conc. aqueous  $\text{NH}_3$  (Liubawin, *J. R.* 15, 17).

12. By digestion of indigo with conc.  $\text{H}_2\text{SO}_4$  or with slightly fuming  $\text{H}_2\text{SO}_4$  a mono-sulphonic acid  $\text{C}_{16}\text{H}_9\text{N}_2\text{O}_2(\text{SO}_3\text{H})$  (phenicoinic-sulphuric acid) and a di-sulphonic acid  $\text{C}_{16}\text{H}_8\text{N}_2\text{O}_2(\text{SO}_3\text{H})_2$  (sulphindigotic acid) are formed.

13. By reduction to leucindigo (indigo-white) and distillation with zinc-dust it gives a mixture of indole  $\text{C}_8\text{H}_7\text{NH}\text{CH}$  and scatole

$\text{C}_8\text{H}_7\text{NH}\text{CH}$  (Baeyer, *B.* 13, 2639).

**Detection of indigo on fabrics.**

(W. Lenz, *Fr.* 26, 535; Prior, *Rep. d. Anal. Chem.* 13, 193, 1884.)

1. A drop of nitric acid gives a bright yellow spot.

2. When indigo alone is present the following reactions should be given: alcohol extracts no colour even on gentle warming. Cold saturated oxalic acid and borax solutions, 10 p.c. alum solution, and 33 p.c. ammonium molybdate solution, removes no colour even on boiling. Stannous and ferric chloride destroy the colour on warming. Glacial acetic acid dissolves all the colour on repeated boiling, and after mixing the solution with ether and water the aqueous layer is colourless and not coloured by strong hydrochloric acid. When the indigo may be accompanied by other colours the following methods of testing may be adopted.

3. The stuff is warmed with an acidified 10 p.c. solution of  $\text{SnCl}_4$ . Prussian blue remains unchanged. Indigo (vat-blue), indigo-carmin, and aniline-blue (triphenyl-methylene-trisulphonate) are completely removed from the fibre, and yield pale-yellow solutions. Logwood is also removed, but gives a rose-red solution. On adding a large excess of hydrogen peroxide to these solutions the rose-red of logwood is destroyed, aniline-blue gives a blue solution, whilst indigo is not regenerated.

4. Glacial acetic acid dissolves indigo from a fabric. In presence of logwood the cold acid requires a rose-red colour, which on heating passes into yellowish-red, and is soon obscured by the dissolving indigo. Prussian blue and indigo

carmine are not dissolved. On mixing the acetic acid solution with ether, and then adding water until the ether separates, the indigo is removed from the aqueous layer, which then in the presence of logwood shows a feeble reddish-yellow tint. If now a few drops of conc. HCl are added, the smallest trace of logwood is revealed by the production of a rich red colour in the aqueous layer. Aniline-blue obscures this reaction.

**Estimation.**—In fabrics: The dyed stuff (10 g.) is treated in a flask with 200 c.c. of a solution made by adding 2 litres of water and 100 c.c. of milk of lime to 100 cc. of a solution of  $\text{Na}_2\text{SO}_3$  prepared from a solution of sodium bisulphite of 35° B. The mixture is heated at 60°–70°, a stream of coal gas being passed through the flask during the reduction. When all the colour has disappeared, a portion of the solution is decanted, cooled, its volume measured, the indigo precipitated by HCl, and after 12 hours standing collected on a filter, washed, and dried. It is then dissolved with the filter-paper in about 10 c.c. of fuming  $\text{H}_2\text{SO}_4$ , and the solution titrated by the hydrosulphite (Müller's) method (*v. infra*) (Renard, *Bl.* 47, 41).

In commercial indigo: 1. The indigo is reduced to leucindigo (indigo-white) by glucose and NaOH in an aqueous alcoholic solution; the clear solution is separated from the insoluble impurities, and by oxidation with a stream of air the indigo is precipitated and weighed (Rau, *Am. C. J.* 7, 16; Manley, *Chem. Centr.* 1887, 605; Romen's *Journal*, 1887, 16). This gives the value in indigo-blue only, as the indirubin remains in the alcoholic solution (Rawson, *S. C. I.* 1885, 491).

2. By reduction with  $\text{FeSO}_4$  and NaOH and subsequent oxidation (Graess-Calvert).

3. By reduction with sodium hydrosulphite  $\text{Na}_2\text{SO}_3$ , and subsequent oxidation by air. The finely powdered indigo (1 g.) is made into a paste with water and placed in a flask with 500–600 c.c. of lime water; the flask is closed with an indiarubber stopper bored with four holes, one carrying a syphon, another a tap-funnel, the remaining two serve for the entrance and exit of a current of coal gas. The whole is heated at 80°, and 100–150 c.c. of sodium hydrosulphite (equivalent to 25 grammes of copper solution containing 19.04 g. of  $\text{CuSO}_4$  per litre) is introduced, and kept near the boiling-point for half an hour. After allowing to settle 500 c.c. of the clear liquid are siphoned off, oxidised by aspirating air through it for 20 mins., an excess of HCl added, and the precipitate of indigo and indirubin washed and weighed. The liquid remaining in the flask is measured, and from it is calculated the combined percentages of indigo and indirubin. If the proportion of indirubin is required the filter and precipitate are extracted with alcohol, which dissolves the indirubin. This method gives very good results (Rawson, *C. N.* 67, 7, 19, 29, 34; *S. C. I.* 1885, 493).

4. The indigo is sulphonated and the solution is reduced by a solution of sodium hydrosulphite of known strength, the excess of which is then estimated by titration with ammoniacal  $\text{CuSO}_4$  (Müller, *J.* 1074, 1019; *Ant. Chemist*, 5, 128; Bernthsen a. Drews, *B.* 18, 2288; Rawson, *S. C. I.* 1885, 490).

5. By sulphonation and subsequent oxidation of the sulphonic acid by means of potassium ferricyanide (Allgren), chlorine-water (Bolley),  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  (Penny), or  $\text{KMnO}_4$  (Mohr). The finely powdered indigo (1 g.) is mixed with an equal weight of ground glass, and gradually added to 20 c.c. of  $\text{H}_2\text{SO}_4$  (S.G. 1.845); it is then placed for 1 hour in a steam-bath at 90°. The sulphuric acid solution is diluted to 1 litre, and 50 c.c. of this diluted solution is mixed with 50 c.c. of water and 32 g. of NaCl. Sodium sulphindigotate being almost insoluble in strong salt solution separates, and after two hours is collected, washed with salt solution (S.G. 1.2), dissolved in hot water, and when cool acidified with 1 c.c. of  $\text{H}_2\text{SO}_4$ , then diluted to 300 c.c., and titrated with  $\text{KMnO}_4$  (5 g. per litre). A small correction (+1.6 p.c.) has to be made for the sulphindigotate which remains in the salt solution; the result gives the combined percentages of indigo and indirubin (Rawson, *S. C. I.* 1885, 489).

6. By loss of weight on sublimation (Lee, *Am. C. J.* 6, 185). According to Rawson (*l.c.*) this method is not accurate, since the other compounds present in the crude indigo affect the result; with inferior qualities the result is often too high, whilst in superior qualities it is too low.

7. By spectrum analysis: 5 g. of the sample is sulphonated and diluted to a litre. This solution is then further diluted according to its depth of colour, and is examined spectroscopically in a layer of 1 c.c. thickness. The coefficient of extinction is directly proportional to the percentage of pure indigo present (Visserdt; Wolff, *Fr.* 17, 310; 23, 29; *D. P. J.* 258, 256).

8. By sulphonation and quantitative dyeing on wool or silk (Chevreul).

**Dyeing methods.**—Indigo-blue is used for dyeing silk, wool, and cotton, to which it is applied by the following methods:

1. By vat-dyeing, i.e. reduction of the indigo to leucindigo (indigo-white) by means of some reducing agent, steeping the material in the colourless solution and finally exposing it to the air, by which the leucindigo is oxidised to indigo, which being insoluble remains firmly fixed in the fibre. This is the best method of indigo dyeing, and gives the fastest colours. Various reducing agents are employed to effect the reduction, and of these different 'vats' the following are the most important:

Cold vats (used chiefly for cotton): a. *Blue vat*, composed of indigo (2 pts.), ferrous sulphate (3 to 4 pts.), slaked lime (3 to 5 pts.), and water (200 pts.). b. *Zinc-dust vat*, composed of indigo (2 pts.), zinc-dust (1 pt.), slaked lime (1 pt.), and water (200 pts.). c. *Hydrosulphite vat*, composed of indigo (1 pt.), 20 p.c. of lime-milk (1 to 1½ pts.), and the sodium hydrosulphite solution ( $\text{Na}_2\text{SO}_3$ ), obtained by reducing 8–10 kilos of sodium bisulphite solution (S.G. 1.276) with zinc-dust or zinc foil, the whole being subsequently diluted with water. d. *Tin salt vat* ( $\text{SnCl}_2$  and an alkali) is only used for printing. e. *Arsenic vat* ( $\text{As}_2\text{O}_3$  and an alkali) is only used for printing (*English Patent* 1884, 421; *S. C. I.* 1885, 58). f. *Sugar vat* (glucose and an alkali).

Warm or fermentation vats (only used for wool and silk): a. *Wood vat*, composed of

Indigo (15 pts.), wood (800 pts.), bran (10 pts.), madder (2 to 15 pts.), slaked lime (12 pts.), and water (4,000 pts.). The liquid is allowed to ferment for about two days, keeping the temperature at 46°-50°, and the vat is then ready for use. *b. Potash Vat*, composed of indigo (10 pts.), madder (3 to 5 pts.), bran (2 to 5 pts.), and K<sub>2</sub>CO<sub>3</sub> (10 to 15 pts.), and water (4,000 pts.), the whole being left to ferment for two days. *c. Soda vat*, composed of indigo (10 pts.), bran (60 to 100 pts.), or treacle (10 to 15 pts.), soda crystals (Na<sub>2</sub>CO<sub>3</sub> 106d) (20 pts.), slaked lime (5 pts.), and water (4,000 pts.), fermented for two or three days.\* For other methods of preparing vats v. Goppelsröder, *D. P. J.* 1897, 465; 255, 245, 381; C. S. I. 1894, 618; Collin *a. Benois*, *German Patent* No. 449; C. S. I. 1886, 498; Schöckert, *English Patent* 1897, 7433.

Indigo is also applied to fabrics:

2. By printing with a paste of reduced indigo and developing the indigo by exposure to air.

3. By printing with a paste of sodium o-nitro-phenyl-propionate, sodium or zinc oxanate, borax, and a thickening agent, the colour being slowly developed by leaving the material at the ordinary temperature for two days. (Bad. Anil. n. Soda-Fabrik, E. P. 1881, 466; *U. S. C. I.* 1882, 148, 360; 1885, 454). The blue obtained in this way surpasses in purity of shade that obtained with natural indigo, and also has the advantage that it can be readily employed in conjunction with other steam colours, *alizarin*, &c.; its high price, however, has hitherto prevented its extended application.

4. By dyeing from a bath of indigo-disulphonic acid ('sulphindigotic acid,' 'indigo-carmines' or 'indigo-extract'). This method is only employed for wool and silk, as the sulphindigotic acid has no affinity for cotton. The colour obtained by this method, called 'Saxony blue,' although much brighter than 'vat-blue' is not nearly so fast either to soap or light.

**Constitution.**—The determination of the constitution of indigo is mostly due to A. Baeyer and his pupils. The molecular formula  $C_{16}H_{10}N_2O_2$  was established by the vapour density determinations of Sommeprg. Isatin  $C_{12}H_6NO_2$ , which is obtained from indigo by oxidation, gives on treatment with reducing agents diindole  $C_{12}H_{10}NO$ , oxindole  $C_{11}H_7NO$ , and finally indole  $C_8H_7N$  (Baeyer, A. Knop, A. 140, 1, 295). From this Baeyer concluded at that time that indole was the parent substance of the dye-stuff, and represented the latter by the formula  $\begin{matrix} C_6H_4CHN \\ | \\ C_6H_4CHN \end{matrix} O$ . Soon afterwards Streaker proposed for indigo the formula

$\text{C}_6\text{H}_5 \cdot \langle \text{NH} \cdot \text{CO} \cdot \text{CO} \cdot \text{NH} \cdot \rangle \cdot \text{C}_6\text{H}_5$ . In 1869 Kekulé (*B.* 2, 748) had assigned to isatin and isatic acid the formula  $\text{C}_6\text{H}_5 \cdot \langle \text{NH} \cdot \text{CO} \cdot \text{CO} \cdot \text{NH} \cdot \rangle \cdot \text{COOH}$  and

$\text{O}_2\text{H} \begin{smallmatrix} \text{CO.OO.H} \\ \text{NH}_2 \end{smallmatrix}$ , thus explaining their ready conversion into  $\alpha$ -amido-benzoic acid and salicylic acid, and this view was subsequently confirmed by the investigations of Baeyer & Suida (B. 11, 582, 1228) and of Claisen & Shadwell (B. 12, 850). At the same time it was proved

that dioxindole and oxindole were respectively the inner anhydrides of *o*-amido-mandellic acid and of *o*-amido-phenyl-acetic acid, and hence were constituted thus:  $C_6H_4 \cdot \begin{matrix} \text{CH(OH)} \\ \text{NH} \end{matrix} \cdot CO$

(*Azoxindole*),  $C_8H_7\langle\begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix}\rangle\text{EO}$  (*oxindole*). In 1870 Baeyer & Emmerling (B. 3, 517) assigned to indole the formula  $C_8H_7\langle\begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix}\rangle\text{OH}[1,2]$ . In the same year Emmerling & Engler (B. 3, 885; cf. B. 9, 1106, 1422) obtained small quantities of indigo by distilling nitro-acetophenone with zinc-dust and soda-lime, from which they concluded that it was an azo-compound, and represented it by the formula  $C_8H_7\langle\begin{smallmatrix} \text{CO.CH:CH.CO} \\ \text{N} \end{smallmatrix}\rangle\text{N}$ ,  $C_8H_7$  leucindigo, being the corresponding hydrazo-compound  $C_8H_7\langle\begin{smallmatrix} \text{CO.CH:CH.CO} \\ \text{NH} \end{smallmatrix}\rangle\text{NH}$ . In 1878 Sommaruga (A. 194, 107) proposed the

formula  $\text{C}_6\text{H}_5\text{--}\overset{\text{O}}{\overset{\text{O}}{\text{N} \text{---} \text{CH} \text{---} \text{CH} \text{---} \text{N}}} \text{--}\overset{\text{O}}{\overset{\text{O}}{\text{C}_6\text{H}_5}}$ ; in 1879 Baumann & Tiemann suggested that indigo might be a derivative of diphenyl:

$$\text{HC} \begin{array}{c} \diagup \text{O} \\ \diagdown \end{array} \begin{array}{c} \diagup \text{O} \\ \diagdown \end{array} \text{H}_2\text{C} \cdot \text{C}_6\text{H}_4 \begin{array}{c} \diagup \text{O} \\ \diagdown \end{array} \text{CH}; \text{ whilst in 1982}$$

Ljubavin (B. 15, 248, 728), regarding indigo as a substitution product of indoline  $C_8H_7N$ , proposed for it the formula:  $C_8H_5N_2O_2$ .

Baeyer's syntheses of indigo in 1882 from indoxyl and diisatogen (*B.* 15, 54) led him to conclude that it had the constitution

$\text{C}_6\text{H}_5\text{---}\begin{array}{c} \diagup \text{C} \diagdown \\ \diagdown \text{N} \diagup \end{array}\text{---O---O---}\begin{array}{c} \diagup \text{C} \diagdown \\ \diagdown \text{N} \diagup \end{array}\text{---C}_6\text{H}_5$ , but his subsequent researches (B. 16, 2200; 17, 975) caused him to modify this formula to

$C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C \begin{smallmatrix} \diagup C \\ \diagdown HN \end{smallmatrix} C_6H_5$ , representing it as the indigenide of  $\psi$ -isatin or diindogen. The latter formula which is now tolerably well established is based upon the following considerations: i. Indigo contains an NH group. ii. The carbon atoms are arranged in a line  $C_6H_5.C.C.C.C.C_6H_5$ , as follows from its formation from di-phenyl-diacyetene. iii. It can only be obtained from compounds in which the carbon atom directly united to the benzene nucleus is also united to O, or capable of becoming so united. iv. Its formation and properties indicate a close relationship to the  $\beta$ -indigenide of ethyl- $\psi$ -isatin  $C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C \begin{smallmatrix} \diagup C \\ \diagdown C \end{smallmatrix} \begin{smallmatrix} \diagup CO \\ \diagdown CH \end{smallmatrix} NEt$ , and to indirubine, which is proved to be the  $\beta$ -indigenide of  $\psi$ -isatin  $C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C \begin{smallmatrix} \diagup C \\ \diagdown C \end{smallmatrix} \begin{smallmatrix} \diagup CO \\ \diagdown CH \end{smallmatrix} NH$ .

The two latter bodies are formed by direct condensation of indoxyl  $\text{C}_6\text{H}_5\langle\frac{\text{O}}{\text{NH}}\rangle\text{OH}$  with ethyl- $\psi$ -isatin  $\text{C}_6\text{H}_5\langle\frac{\text{CO}}{\text{NH}}\rangle\text{CO}$ , or with isatin  $\text{C}_6\text{H}_5\langle\frac{\text{CO}}{\text{NH}}\rangle\text{C(2H)}$ , in which reactions the indoxyl is probably first transformed into  $\psi$ -indoxyl  $\text{C}_6\text{H}_5\langle\frac{\text{CO}}{\text{NH}}\rangle\text{OH}$ , and the isatin into  $\psi$ -isatin

$\text{C}_6\text{H}_5\text{CO} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{CO}$ . Combination then takes place between the  $\alpha$ -carbon atom of the  $\psi$ -indoxyl acid and the  $\beta$ -carbon atom of the  $\psi$ -isatin, thus:

$= \text{C}_6\text{H}_5\text{CO} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{CO} \\ \text{HN} \end{smallmatrix} \text{C}_6\text{H}_5$ . Indigo is consequently the isomeric  $\alpha$ -indogenide of  $\psi$ -isatin, though it cannot be formed from isatin and indoxyl owing to the greater tendency to reaction of the  $\beta$ -CO group.

**Substitution products.** Indigo-mono-sulphonic acid  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}_5(\text{SO}_3\text{H})$ . *Phenicine-sulphuric acid*. Formed by allowing to stand for some time a mixture of indigo (1 pt.) with ordinary sulphuric acid (20 pts.), and separates as a blue powder on pouring the solution into water. It is easily soluble in alcohol, and in water free from acid, forming blue solutions. Its salts are sparingly soluble in water. In the dry state they are red, in solution blue.—A'Kaq: purple pp. (Crum, *Bers. J.* 4, 189; Berzelius, *Bers. J.* 4, 190; 7, 262; Dumas, *A.* 48, 340; Reesfeldt, *Gm.* 6, 462).

Indigo-di-sulphonic acid  $\text{C}_{10}\text{H}_5\text{N}_2\text{O}_7(\text{SO}_3\text{H})_2$ . *Sulphindigotic acid*. *Oerulins-sulphuric acid*. *Indigo-extract*. Prepared by heating indigo with 15–20 pts. of ordinary, or better with 7–8 pts. of fuming, sulphuric acid. Amorphous blue solid. V. sol. water and alcohol. Completely removed from solution by wool or charcoal. The aqueous solution gives a continuous absorption spectrum (Vogel, *B.* 11, 1365). By oxidising agents it is converted into isatin sulphonic acid, by reducing agents into leucoindigo-sulphonic acid. Its salts are mostly sparingly sol. water. The sodium salt ( $\text{A}''\text{Na}$ ) appears in commerce under the name of *indigo-carmin* or *soluble-indigo* and is used for dyeing the so-called 'Saxony-blue' upon silk and wool.—A'Kq: amorphous blue coppery powder; S. at  $15^\circ$ —7.—A'Ba: m. sol. hot water (Crum, *Bers. J.* 4, 190; Berzelius, *Bers. J.* 7, 262; Dumas, *A.* 22, 72; Joss, *Bers. J.* 14, 316). According to Berzelius (*Gm.* 6, 456) there is formed, together with the di-sulphonic acid, another acid, the so-called '*indigo-hyposulphuric acid*,' which differs from the di-sulphuric acid in its ammonium salt being soluble in water.

Indigo-di-carboxylic acid  $\text{C}_{10}\text{H}_5\text{N}_2\text{O}_8$ . *i.s.*

Prepared by waffining nitro-benzaldehyde-carboxylic acid  $\text{C}_6\text{H}_4(\text{CHO})(\text{NO}_2)\text{CO}_2\text{H}$  (1:2:4) with acetone and dilute NaOH. Also by reduction of  $\psi$ -nitro-phenyl-propionic-carboxylic acid  $\text{C}_6\text{H}_4(\text{NO}_2)(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  with glucose and NaOH. Coarse blue powder. Insol. water, alcohol, ether, and chloroform. Dissolves in  $\text{H}_2\text{SO}_4$  with a deep-blue colour, in alkalis with a bluish-green colour.—A'Ba:  $\text{C}_{10}\text{H}_5\text{N}_2\text{O}_8\text{Ag}$ : insoluble.—A'Kq: sublimes in prismatic tables, at self chloroform and benzene, nearly insol. alcohol and ether (Löw, *B.* 18, 960; *A.* 281, 866).

Di-chloro-indigo  $\text{C}_{10}\text{H}_3\text{Cl}_2\text{N}_2\text{O}_8$ . Obtained by the action of acetone and NaOH upon chloro-*o*-nitro-benzaldehyde (Müller, *German Patents* 30,329 and 38,064).

Tetra-chloro-indigo  $\text{C}_{10}\text{H}_1\text{Cl}_4\text{N}_2\text{O}_8$ . *i.s.*

$\text{C}_6\text{H}_3\text{Cl}_4\text{N}_2\text{O}_8$ . Obtained by the action of acetone and NaOH upon di-chloro-*o*-nitro-benzaldehyde [1887] (*Ind. Anl. u. Soda-Fabrik, G. P.* 82,238). Resembles indigo. Sublimes in violet-red vapours, condensing to blue coppery needles. Does not sulphonate or form a 'vat' so readily as ordinary indigo (Gnehm, *B.* 17, 753).

Di-bromo-indigo  $\text{C}_{10}\text{H}_3\text{Br}_2\text{N}_2\text{O}_8$ . *i.s.*

Formed by adding bromo-isatin chloride (from bromo-isatin and  $\text{PCl}_5$ ) to an excess of an 8 p.c. solution of HI in acetic acid (Baeyer, *B.* 12, 1815). Also obtained by boiling the acetyl derivative of tribromo-*b*-amido-acetophenone with  $\text{Na}_2\text{CO}_3$  (Baeyer & Bloom, *B.* 17, 368). Soluble in phenol, from which it separates on adding alcohol in small black needles. Nearly insol. alcohol, ether, acetic acid, or chloroform. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a green colour. Sublimes in purple vapours. Forms a 'vat' like indigo. The absorption spectrum is the same as that of indigo.

Di-nitro-indigo  $\text{C}_{10}\text{H}_3(\text{NO}_2)_2\text{N}_2\text{O}_8$ . *i.s.*

Formed by adding nitro-isatin chloride (from nitro-isatin and  $\text{PCl}_5$ ) to a solution of HI in acetic acid. Dark-red powder. Nearly insol. alcohol, ether, acetic acid, and chloroform; v. sol. phenol and hot nitrobenzene. The absorption spectrum is analogous to that of indigo. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a violet-blue colour (Baeyer, *B.* 12, 1815).

Di-amido-indigo  $\text{C}_{10}\text{H}_3\text{N}_4\text{O}_8(\text{NH}_2)_2$ . *i.s.*

Formed by reduction of the foregoing nitro-compound with zinc-dust and acetic acid. Dark-blue pp. Nearly insol. alcohol, ether, and chloroform; v. sol. acetic acid with a pure blue colour. Its absorption spectrum is like that of indigo. It dissolves in dilute acids with a blue colour. It forms a 'vat' like indigo.

Di-benzoyl-indigo  $\text{C}_{10}\text{H}_3\text{N}_2\text{O}_8$ . *i.s.*

$\text{C}_6\text{H}_5\text{CO} \begin{smallmatrix} \text{CO} \\ \text{NBz} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{CO} \\ \text{NBz} \end{smallmatrix} \text{C}_6\text{H}_5$  [1087]. Formed by heating indigo with  $\text{BzCl}$ . Brown amorphous powder. Insol. water and acetic acid, al. sol. alcohol, m. sol. ether (Schwartz, *J.* 1863, 557).

Di-methyl-indigo  $\text{C}_{10}\text{H}_5\text{Me}_2\text{N}_2\text{O}_8$ . *i.s.*

$\text{C}_6\text{H}_5\text{Me} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{CO} \\ \text{HN} \end{smallmatrix} \text{C}_6\text{H}_5\text{Me}$ . Formed by the action of acetone and NaOH upon *o*-nitro-tolualdehyde. Blue coppery powder. Sol. alcohol. Resembles ordinary indigo (Meister, *Lugins & Brünings, G. P.* 21,683; *E. P.* 152, 270).

Di-ethyl-indigo  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}_8$ . *i.s.*

$\text{C}_6\text{H}_5 \begin{smallmatrix} \text{CO} \\ \text{NEt} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{CO} \\ \text{NEt} \end{smallmatrix} \text{C}_6\text{H}_5$ . Prepared by reducing the di-ethyl derivative of  $\psi$ -isatin-oxim  $\text{C}_6\text{H}_5 \begin{smallmatrix} \text{CO} \\ \text{NEt} \end{smallmatrix} \text{C}(\text{NOEt})$  with alcoholic ammonium sulphide, and then passing a stream of  $\text{CO}$  through the solution. Blue scaled needles; v. sol. alcohol, forming a deep-blue solution, the spectrum of which closely resembles that of indigo. Less soluble in ether, acetone,  $\text{CHCl}_3$ ,  $\text{CS}_2$ , and aniline. It sublimes as a purple vapour.

Di-isopropyl-indigo  $C_{22}H_{27}N_2O_2$ , i.e.

Tetra-methoxy-indigo-di-carboxylic acid  
 $C_{22}H_{16}N_2O_{10}$

### Allied compounds.

Leucoindigo  $C_{15}H_{13}N_2O_2$  i.e.  
 $C_6H_5 \langle \begin{smallmatrix} C(OH):C:C(OH) \\ | \quad \quad | \\ NH \quad \quad HN \end{smallmatrix} \rangle C_6H_5$  (?).

**Lecundindisulphuric acid.** *Indigo-white-sulphuric acid.* The potassium salt is obtained by shaking damp pressed leucindigo (25 g.) dissolved in 25 g. of aqueous KOH (2) with 12-15 g. of  $\text{H}_2\text{SO}_4$ . The solution is diluted with an equal bulk of water, exposed to the air, filtered from indigo, shaken with ether, and freed from potassium sulphate by mixing with six times its volume of absolute alcohol (Bayer, B. 19, 1600; Baumann & Tiemann, B. 13, 411). By the action of air or  $\text{FeCl}_3$  it is oxidised to indigo. The solution of the K salt is resolved by dilute acids into leucindigo and  $\text{H}_2\text{SO}_4$ . This com-

Indican  $C_{15}H_{11}NO$ , (?). Plant indican.

*Guaecoides of indigo* or *Indigo*. Occurs in the *Indigofera*, in *Isatis tinctoria* (wood), *Polypodium linetorum*, *Blechna tectorica*, *Callanthus veratrifolia*, and other plants (Schnuck, J. 1886, 659; 1853, 468; C. N. 87, 238). Prepared by extracting dried and powdered wood leaves with cold alcohol. The extract treated with a little water is evaporated at the ordinary temperature of the air, the aqueous residue shaken with CuO, filtered, freed from copper by H<sub>2</sub>S, filtered, and again evaporated in the cold. The syrup is taken up with alcohol, precipitated with twice its volume of ether, and the filtrate evaporated at the ordinary temperature. Light-brown syrup. Slightly bitter taste. Sol. water and alcohol. In alcoholic solution it gives a yellow pp. with lead acetate. Boiled with KOH it evolves NH<sub>3</sub>. By long boiling with water it is decomposed. It is composed by baryta water in the cold with formation of a syrupy body called *inducanine* C<sub>12</sub>H<sub>11</sub>NO<sub>11</sub> (?). By heating with dilute acids it is resolved into *indigo* and *indigulin* (a sugar). Simultaneously are formed *indirubin* C<sub>12</sub>H<sub>7</sub>N<sub>3</sub>O<sub>5</sub>, *indirubin* C<sub>12</sub>H<sub>7</sub>N<sub>3</sub>O<sub>5</sub> (dark-brown resin, sol. alcohol), *indisfulvin* (reddish-yellow resin, insol. alkalis), *induhumin* C<sub>12</sub>H<sub>7</sub>N<sub>3</sub>O<sub>5</sub> (brown powder, insol. water and alcohol, sol. alkalis), *indufuscin* C<sub>12</sub>H<sub>7</sub>N<sub>3</sub>O<sub>5</sub> (analogous to inhumine), acetic acid, formic acid, and CO. (Schnuck & Römer, B. 12, 2811; C. N. 39, 119). When fresh indian solution is mixed with strong acid and boiled, only indigo and indigulin are obtained, but if the indian solution is previously boiled for a short time indirubin is also formed (Schnuck. C. J. 85, 628).

The name 'indican' has also been erroneously given to indoxyl-sulphuric acid which is a normal constituent of the urine of animals (Baumann & Tiemann, *B.* 12, 1098; 13, 511).

Indirubin  $C_{16}H_{10}N_2O$ , i.e.

$$\begin{array}{c} \text{C}_6\text{H}_5 \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C} \text{---} \text{O} \text{---} \text{C} \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_5 \end{array} \text{NH} \text{ or} \\ \text{C}_6\text{H}_5 \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C} \text{---} \text{O} \text{---} \text{C} \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_5 \end{array} \text{N} \end{array} \quad \text{Indipurpurin.}$$

**Indigo-red.**  $\psi$ -**Isatin** = **indogenin**. Forms together with indigo when a solution of indacin, previously boiled for a short time, is treated with an acid. Also together with indigo by the action of zinc-dust and acetic acid upon isatin-chloride. Obtained synthetically by condensation of isatin and indoxyl. An indoxyl solution prepared by boiling 1 pt. of indoxyl in 100 pts. of water for a short time is filtered into a solution of  $\frac{3}{4}$  pt. of isatin in 200 pts. of boiling water. Na<sub>2</sub>CO<sub>3</sub> is added to the precipitated indirubin is filtered off and washed. Needles. Sol. alcohol, ether, benzene, and acetic acid forming purple solutions; insol. water. Begins to sublime at 140°; condensing in fine reddish needles (Schunck, *J. J.* 87, 817). Gives an absorption spectrum which is different from that of indigo. Forms 2 vat. Is more stable towards oxidizing agents than indigo. By zinc-dust and acetic acid it is reduced first to leucindirubin,  $C_{16}H_{14}N_2O_2$ , and finally to indirubin  $C_{16}H_{12}N_2O$  (Schunck, *B.* 13, 1230; *C. N.* 39, 119; *Beauver.* *B.* 13, 457; 14, 1745; 15, 50; 16, 3900).

# INDIGO.

The *bromo-derivative*  $C_{11}H_7BrN_2O_2$  from indoxyl and bromisatin resembles indirubin.

The *di-bromo-derivative*  $C_{11}H_5Br_2N_2O_2$  is obtained in very small quantity together with dibromindigo by reduction of bromisatin chloride with HI. Needles: sol. alcohol and ether (Baeyer, B. 12, 1815).

The *di-nitro-derivative*  $C_{11}H_7(NO_2)_2N_2O_2$  is formed in small quantity together with nitro-indigo by reduction of nitroisatin chloride with HI. Sol. alcohol with a red colour.

Ethyl-indirubin  $C_{13}H_{11}N_2O_2$ , s.s.

$C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C_6H_5$  NEt. *a-Indogenide of ethyl-ψ-isatin*. [198°]. Prepared by adding a

hot aqueous solution of indoxyl to a hot aqueous solution of ethyl-ψ-isatin mixed with HCl; brownish-red needles of the product separate at once (Baeyer, B. 16, 2200). Coppery needles: sol. chloroform to a red solution, s. sol. alcohol and acetone. Dissolves in conc.  $H_2SO_4$  with a brown colour which becomes violet on heating with formation of a sulphuric acid. It gives a 'vat' with zinc-dust and alkalis.

Indilenein  $C_{11}H_7N_2O_2$ , s.s.

$C_6H_5 \begin{smallmatrix} \diagup O(OH) \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup C(OH) \\ \diagdown NH \end{smallmatrix} C_6H_5$  NH or

$C_6H_5 \begin{smallmatrix} \diagup OH \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup C(OH) \\ \diagdown NH \end{smallmatrix} C_6H_5$  NH. Obtained by

reduction of indirubin with zinc-dust and acetic acid; the yield is 35 p.c. Colourless glistening needles; sol. acetic acid, sl. sol. alcohol, ether, benzene, and chloroform.  $FeCl_3$  gives an intense yellowish-green colour. Nitrous acid colours the acetic acid solution orange. Picrate  $C_{11}H_7N_2O_6$ ,  $H_2(NO_3)_2$ : orange crystals. Methyl ether  $C_{11}H_{11}N_2(OMe)_2$ : [192°]; large glistening prisms; sol. alcohol and ether. Triacetyl derivative  $C_{11}H_7Ac_3N_2$ : [278°]; flat yellow needles (Forrer, B. 17, 977).

Iso-indilenein  $C_{11}H_7N_2O_2$ , s.s.

$C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup C(OH) \\ \diagdown NH \end{smallmatrix} C_6H_5$  CH<sub>2</sub>NH (?) [192°]. Formed

by shaking a benzene solution of *o*-di-bromoacetophenone  $C_6H_4CO_2Br_2$  with strong aqueous  $NH_3$ . Yellow mass. Sol. hot alcohol, insol. water, and cold benzene. Weak base. It gives a red coloration on the addition of phenol to  $H_2SO_4$  solution. By reduction in alcoholic solution with tin and HCl it yields hydroindilenein. Picrate  $C_{11}H_7N_2O_6$ ,  $H_2(NO_3)_2$ : [150°]; yellow needles (Engler & Hassenkamp, B. 18, 2241).

Hydro-iso-indilenein  $C_{11}H_7N_2O_2$ , s.s.

$C_6H_5 \begin{smallmatrix} \diagup OH \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup C(OH) \\ \diagdown NH \end{smallmatrix} C_6H_5$  CH<sub>2</sub>NH (?) [160°]

with decomposition. Formed by the action of tin and HCl on an alcoholic solution of isoindirubin. Plates. V. sol. alcohol, ether, and  $CHCl_3$ . Sol.  $H_2SO_4$  with a blue colour. Oxidises back to isoindirubin by treatment with  $CrO_3$ .

Methyl-iso-indilenein  $C_{11}H_{11}MeN_2O_2$ . [115°] Formed by heating isoindirubin with MeI, at alcoholic KOH at 100°-110°. Plates. Sol. alcohol and ether. No colouration with  $H_2SO_4$ , as phenol (Engler & Hassenkamp, B. 18, 2249).

Indolin  $C_{11}H_7N_2O_2$ . Formed by adding  $FeSO_4$  to a solution of *o*-nitro-phenyl-propionic acid in  $H_2SO_4$ , or by the action of the propionic acid on an  $H_2SO_4$  solution of indoxyl. Also by action of  $FeSO_4$  and conc.  $H_2SO_4$  upon *o*-di-nitro-phenyl-diastyle  $C_6H_4(NO_2)_2C_6H_4C_6H_4C_6H_4$  (NO or upon the isomeric diastogen  $C_6H_4N_2O_2$ ; at by treatment of isatogen-sulphurous acid with conc.  $H_2SO_4$ . Blue dyestuff, resembling indigo in many points. Dissolves in cold  $H_2SO_4$  with blue colour, but is not readily sulphated. Also dissolves to a blue solution in cold aniline or aqueous  $SO_2$ . Combines with  $SO_2$ . Gives 'vat' (Baeyer, B. 14, 1742; 15, 52, 57, 212).

Indoline  $C_{11}H_7N_2$ , s.s.

$C_6H_5 \begin{smallmatrix} \diagup OH \\ \diagdown NH \end{smallmatrix} C_6H_5 \begin{smallmatrix} \diagup NH \\ \diagdown CH \end{smallmatrix} C_6H_5$  Diindole. [245°]

Formed by heating leucindigo (indigo-white (1 pt.) with barium hydrate (3 pts.), zinc-dust (1½ pts.) and water (18½ pts.) for 24 hours at 180° (Schützenberger, J. 1877, 511); the product is extracted with alcohol, the alcohol evaporated and the residue heated with zinc-dust when indoline sublimes. More readily obtained by reduction of flavindine dissolved in dilute NaOH, with 5 p.c. sodium amalgam (Graud, J. 1880, 586). Long yellow needles by sublimation. Sol. alcohol and ether with a blue fluorescence, insol. water. Forms salts with acids. The picrate  $C_{11}H_7N_2O_6$ ,  $H_2(NO_3)_2$  is sl. sol. alcohol.

Di-chloro-indoline  $C_{11}H_7Cl_2N_2$ . Got by passing Cl into a  $CHCl_3$  solution of indoline.

Di-nitro-indoline  $C_{11}H_7(NO_2)_2N_2$ . Got by dissolving indoline in warm nitric acid. Crystallises from alcohol in orange-yellow crystals.

Indoline-di-sulphonic acid  $C_{11}H_7(SO_3H)_2N_2$  is formed by heating indoline with fuming  $H_2SO_4$  at 180°. Its sodium salt  $Na_2$  is crystalline.
